

## On the index of certain standard congruence subgroups

Thomas Morgan

ABSTRACT. For an epimorphism of the free group on two generators onto a finite group  $G$ , one can associate a finite index subgroup of the automorphism group of the free group called the standard congruence subgroup. We calculate the index of this group when  $G$  is a non-abelian semi-direct product of cyclic groups of prime order.

### 1. Introduction

There is a well-known surjective representation of the automorphism group of a free group  $\rho_0 : \text{Aut}(F_n) \rightarrow \text{Aut}(F_n/[F_n, F_n]) \cong \text{GL}_n(\mathbb{Z})$ . The kernel of this representation is called the *Torelli subgroup*, denoted  $IA(F_n)$ , and the subgroup of  $\text{Aut}(F_n)$  whose elements have determinant 1 under  $\rho_0$  is called the *special automorphism group*, denoted  $\text{Aut}^+(F_n)$ . While this linear representation of  $\text{Aut}^+(F_n)$  is well studied, only a few other representations were studied until 2006, when Grunewald and Lubotzky[GL09] published a paper detailing the construction of a family of virtual linear representations of  $\text{Aut}(F_n)$  indexed by finite groups  $G$  and surjective homomorphisms  $\pi : F_n \rightarrow G$ . This gave rise to a generalization of the Torelli subgroup different from the Johnson filtration and proved that  $\text{Aut}(F_3)$  is large, which implies that it does not have Kazhdan's property (T).

*Key words and phrases.* automorphism groups, free groups, congruence subgroups.

In constructing these representations, Grunewald and Lubotzky used the subgroup  $\Gamma(G, \pi) \leq \text{Aut}(F_n)$ . This subgroup is called the *standard congruence subgroup* of  $\text{Aut}(F_n)$  associated to  $G$  and  $\pi$ . The subgroup is defined as follows: let  $R := \ker(\pi)$ . Then the action of  $F_n$  on  $R$  by conjugation leads to an action of  $G$  on the relation module  $\bar{R} := R/[R, R]$ . Define  $\Gamma(G, \pi) := \{\varphi \in \text{Aut}(F_n) \mid \varphi(R) = R, \varphi \text{ induces identity on } F_n/R \cong G\}$ . This is exactly the  $G$ -equivariant automorphisms under this action. It is also analogous to congruence subgroups, which are extensively studied for arithmetic groups.

Following Grunewald and Lubotzky’s paper, Appel and Ribnere [AR09] began a more systematic study of these standard congruence subgroups in the case where  $n = 2$ . First they restricted themselves to  $\Gamma^+(G, \pi) = \Gamma(G, \pi) \cap \text{Aut}^+(F_2)$ . Then they computed the index  $[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)]$  for  $G$  abelian or dihedral. In doing so, and with some further analysis, they gave some partial results to the congruence subgroup problem for  $\text{Aut}^+(F_2)$ . Appel and Ribnere also posed a conjecture stating the index when  $G$  is the non-abelian semidirect product of two cyclic groups of prime order. We prove their conjecture.

**Theorem 1.1.** *Let  $G$  be the non-abelian semidirect product of two cyclic groups,  $G = \mathbb{Z}/p\mathbb{Z} \rtimes \mathbb{Z}/q\mathbb{Z}$ , where  $p$  and  $q$  are primes with  $p \equiv_q 1$ . Then*

$$[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)] = |G| \cdot [SL_2(\mathbb{Z}) : \Gamma_1(q)] = pq(q^2 - 1).$$

Here  $\Gamma_1(q) := \left\{ \begin{bmatrix} \alpha & \beta \\ \delta & \epsilon \end{bmatrix} \in SL_2(\mathbb{Z}) \mid \delta \equiv_q 0, \epsilon \equiv_q 1 \right\}$ . Note that this is true independent of the choice of  $\pi$ . We prove this in Section 2. The second equality follows from the study of congruence subgroups (see for example [DS05]). Then in Section 3, we prove the first equality by using the primitive elements constructed in [OZ81] to construct enough automorphisms in  $\Gamma^+(G, \pi)$  to prove that  $\rho_0(\Gamma^+(G, \pi)) = \Gamma_1(q)$ . The equality then follows from the following proposition from [AR09].

**Proposition 1.2** (Appel, Ribnere). *Let  $\pi : F_2 \rightarrow G$  be an epimorphism of  $F_2$  onto a finite group  $G$ . Then*

$$[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)] = [SL_2(\mathbb{Z}) : \rho_0(\Gamma^+(G, \pi))] \cdot [G : Z(G)].$$

Here  $\rho_0 : \text{Aut}(F_n) \rightarrow \text{Aut}(F_n/[F_n, F_n]) \cong GL_n(\mathbb{Z})$  is the representation introduced earlier.

## 2. Independence of the choice of $\pi$

**2.1. A description of  $\text{Aut}(G)$ .** Let  $p, q \in \mathbb{N}$  be primes such that  $p \equiv_q 1$ . Then the non-abelian semi-direct product  $G := \mathbb{Z}/p\mathbb{Z} \rtimes \mathbb{Z}/q\mathbb{Z}$  has the following presentation:

$$G = \langle a, b \mid a^p = b^q = 1, bab^{-1} = a^\lambda \rangle$$

for some  $1 < \lambda < p$  and  $\lambda^q \equiv_p 1$  ( $\lambda = 1$  would be the abelian case). Indeed, let  $\mathbb{Z}/p\mathbb{Z} = \langle a \rangle$  and  $\mathbb{Z}/q\mathbb{Z} = \langle b \rangle$ . Then the above presentation comes from the outer semi-direct product associated with the homomorphism  $\varphi : \mathbb{Z}/q\mathbb{Z} \rightarrow \text{Aut}(\mathbb{Z}/p\mathbb{Z})$  such that  $\varphi(b)(a) = a^\lambda$ .

Let  $F_2 = \langle x, y \rangle$  be the free group on two generators. To see that the index we wish to calculate is independent of the choice of  $\pi : F_2 \rightarrow G$ , we look at an action of  $\text{Aut}^+(F_2)$  on the following set. We define

$$\mathbf{R}_2(G) := \{\ker(\pi) \mid \pi : F_2 \rightarrow G \text{ is an epimorphism}\}.$$

We can define an action of  $\text{Aut}^+(F_2)$  on  $\mathbf{R}_2(G)$  by

$$\varphi.R := \varphi(R) \text{ for } \varphi \in \text{Aut}^+(F_2), R \in \mathbf{R}_2(G).$$

If the action is transitive, then  $[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)]$  is independent of the choice of  $\pi$ . Indeed, let  $\pi, \pi' : F_2 \rightarrow G$  be epimorphisms, and assume that there is some  $\varphi \in \text{Aut}^+(F_2)$  such that  $\varphi.\ker(\pi) = \ker(\pi')$ . Since  $\varphi.\ker(\pi) = \ker(\pi \circ \varphi^{-1})$ , we have that  $\Gamma^+(G, \pi') = \{\varphi \circ \psi \circ \varphi^{-1} \mid \psi \in \Gamma^+(G, \pi)\}$ . Since  $\Gamma^+(G, \pi)$  and  $\Gamma^+(G, \pi')$  are conjugate subgroups of  $\text{Aut}^+(F_2)$ , we conclude that  $[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)] = [\text{Aut}^+(F_2) : \Gamma^+(G, \pi')]$ .

In order to show that this action is transitive, it is helpful to first understand the automorphisms of the group  $G$ . To that effect, we prove the following lemma.

**Lemma 2.1.** *For each  $0 < i < p, 0 \leq j < p$  there is a unique automorphism  $\varphi_{i,j} : G \rightarrow G$  such that  $\varphi(a) = a^i, \varphi(b) = a^j b$ . Moreover  $\text{Aut}(G) = \{\varphi_{i,j} \mid 0 < i < p, 0 \leq j < p\}$ .*

**Proof.** Let  $0 < i < p, 0 \leq j < p$ . Since  $\{a, b\}$  is a generating set of  $G$ , we can define  $\varphi_{i,j}$  on  $\{a, b\}$  as above and extend to a homomorphism in a unique way. To see this is a well-defined homomorphism, we will check that it satisfies the relations. First, we have that

$$\varphi(a)^p = (a^i)^p = a^{ip} = (a^p)^i = 1^i = 1.$$

Since  $p \nmid (1 - \lambda)$  and  $\lambda^q \equiv_p 1$ , it follows that

$$\varphi(b)^q = (a^j b)^q = a^j a^{j\lambda} \dots a^{j\lambda^{q-1}} b^q = a^r,$$

where

$$r = \sum_{i=0}^{q-1} j\lambda^i = j \sum_{i=0}^{q-1} \lambda^i = j \left( \frac{1 - \lambda^q}{1 - \lambda} \right) \equiv_p 0.$$

Finally, we have that

$$\varphi(b)\varphi(a)\varphi(b)^{-1} = a^j b a^i b^{-1} a^{-j} = a^j a^{\lambda^i} a^{-j} = (a^i)^\lambda = \varphi(a)^\lambda.$$

Thus  $\varphi$  is a homomorphism.

To see this map is surjective, note that  $a^i$  is a generator of  $\langle a \rangle$  for  $0 < i < p$ . It follows that  $a \in \text{Im}(\varphi_{i,j})$ . Then  $a, a^j b \in \text{Im}(\varphi_{i,j}) \implies b \in \text{Im}(\varphi_{i,j})$ . This shows that  $\text{Im}(\varphi_{i,j})$  contains a generating set, so  $\varphi_{i,j}$  is surjective. Because  $G$  is finite, this is enough to show that  $\varphi_{i,j}$  is an automorphism.

Now let  $H$  denote the set  $\{\varphi_{i,j} \mid 0 < i < p, 0 \leq j < p\}$ . We have shown that  $H \subset \text{Aut}(G)$ . Thus it remains to show the reverse inclusion.

Let  $\varphi \in \text{Aut}(G)$ . Since  $\langle a \rangle$  contains all of the elements of order  $p$  in  $G$ ,

$$\begin{aligned} \varphi(a) &= a^i \text{ for some } 0 < i < p. \\ \varphi(b) &= a^j b^k \text{ for some } 0 \leq j < p, 0 < k < q. \end{aligned}$$

On the one hand,

$$\varphi(bab^{-1}) = \varphi(a^\lambda) = a^{i\lambda}.$$

On the other hand,

$$\varphi(bab^{-1}) = \varphi(b)\varphi(a)\varphi(b)^{-1} = a^j b^k a^i b^{-k} a^{-j} = a^j a^{i\lambda^k} b^k b^{-k} a^{-j} = a^{i\lambda^k}.$$

Thus  $a^{i\lambda} = a^{i\lambda^k}$ . Since  $a$  is of order  $p$  and  $p$  does not divide  $i$ , it follows that  $\lambda^{k-1} \equiv_p 1$ . We know that  $\lambda$  is of order  $q$ , so  $q \mid (k-1)$ . But  $0 < k < q$ , so  $k = 1$ . Thus  $\text{Aut}(G) \leq H$ . □

**2.2. Independence of the choice of  $\pi$ .** We will now show that the action of  $\text{Aut}^+(F_2)$  on  $\mathbf{R}_2(G)$  defined above is transitive. This will mean that the index  $[\text{Aut}^+(F_2) : \Gamma^+(G, \pi)]$  is independent of the choice of  $\pi$ . Thus we will be able to compute the index using the epimorphism

$$\begin{aligned} \pi_0 : F_2 &\rightarrow G \\ x &\mapsto a \\ y &\mapsto b \end{aligned}$$

**Lemma 2.2.** *The action of  $\text{Aut}^+(F_2)$  on the set  $\mathbf{R}_2(G)$  is transitive.*

**Proof.** Let  $\pi : F_2 \rightarrow G$  be an arbitrary epimorphism of  $F_2$  onto  $G$ . Then for some  $i, j, k, \ell \in \mathbb{Z}$ , we have  $\pi(x) = a^i b^j$ ,  $\pi(y) = a^k b^\ell$ . Let  $\beta : G \rightarrow \mathbb{Z}/q\mathbb{Z}$ ,  $\beta(a^m b^n) = n$ . Then  $\beta \circ \pi$  is an epimorphism of  $F_2$  onto  $\mathbb{Z}/q\mathbb{Z}$ . The following diagram commutes:

$$\begin{array}{ccccc} F_2 & \xrightarrow{\alpha} & (\mathbb{Z}/q\mathbb{Z})^2 & \xrightarrow{\delta} & (\mathbb{Z}/q\mathbb{Z}) \\ & & \searrow & \nearrow & \\ & & & \beta \circ \pi & \end{array}$$

where  $\alpha(x) = (1, 0)$ ,  $\alpha(y) = (0, 1)$ , and  $\delta(m, n) = mj + n\ell$ . Since  $\delta \circ \alpha$  is surjective, there is an element  $(m, n) \in (\mathbb{Z}/q\mathbb{Z})^2$  such that  $\delta(m, n) = 1$ . Furthermore, since  $\delta$  is not injective, there is a non-zero element  $(u, v)$  such

that  $\delta(u, v) = 0$ . It is clear that  $(m, n)$  and  $(u, v)$  are linearly independent, so  $d := \begin{vmatrix} u & m \\ v & n \end{vmatrix} \not\equiv_q 0$ . Thus we can choose a  $\tilde{d} \in \mathbb{Z}$  such that  $d\tilde{d} \equiv_q 1$ . The vector  $(\tilde{d}u, \tilde{d}v)$  is in the kernel of  $\delta$  since  $(u, v)$  is, and  $M := \begin{pmatrix} \tilde{d}u & m \\ \tilde{d}v & n \end{pmatrix} \in \text{Sl}_2(\mathbb{Z}/q\mathbb{Z})$ .

Choose a matrix  $N \in \text{Sl}_2(\mathbb{Z})$  such that  $N \equiv_q M$ . Let  $\rho_0 : \text{Aut}(F_n) \rightarrow \text{Aut}(F_n/[F_n, F_n]) \cong \text{GL}_n(\mathbb{Z})$  be the homomorphism described in the introduction. Because  $\rho_0$  is surjective, we may choose an automorphism  $\phi \in \text{Aut}^+(F_2)$  such that  $\rho_0(\phi) = N$ . It follows that  $\delta \circ \alpha \circ \phi(x) = 0$ ,  $\delta \circ \alpha \circ \phi(y) = 1$ . Thus  $\pi \circ \phi(x) = a^g$  and  $\pi \circ \phi(y) = a^hb$  for some  $g, h \in \mathbb{Z}$ . By Lemma 2.1,  $\varphi_{g,h}^{-1} \circ \pi \circ \phi = \pi_0$ . It follows that  $\ker(\pi)$ ,  $\ker(\pi_0)$  lie in the same  $\text{Aut}^+(F_2)$  orbit.  $\square$

### 3. Proof of Theorem 1.1

**3.1. Image of primitive elements.** Let  $p, q$  be as above. Now that we know the action of  $\text{Aut}^+(F_2)$  on  $\mathbf{R}_2(G)$  is transitive, we need to show that

$$\rho_0(\Gamma^+(G, \pi_0)) = \Gamma_1(q). \text{ Here } \Gamma_1(q) := \left\{ \begin{bmatrix} \alpha & \beta \\ \delta & \epsilon \end{bmatrix} \in \text{Sl}_2(\mathbb{Z}) \mid \delta \equiv_q 0, \epsilon \equiv_q 1 \right\}.$$

To do this, we use the description of primitive elements from [OZ81] to construct elements of  $\Gamma^+(G, \pi_0)$ . In Section 2 of [OZ], given  $\alpha, \delta \in \mathbb{Z}^+$  such that  $\gcd(\alpha, \delta) = 1$ , Osbourne and Zieschang outline a geometric construction of a primitive element  $v_{\alpha, \delta}$  containing  $\alpha$  copies of  $x$  and  $\delta$  copies of  $y$  which we reproduce here. Draw a directed line segment from  $(0, 0)$  to  $(\alpha, \delta)$ . We use this line segment to generate a word in  $F_2$ . Starting at  $(0, 0)$ , every time the segment passes a vertical integer grid line write an  $x$ , and every time the segment passes a horizontal integer grid line write a  $y$ . Call the resulting word  $v'_{\alpha, \delta}$ . Define  $v_{\alpha, \delta} := xyv'_{\alpha, \delta}$ . Lemma 2.3 of [OZ81] shows that  $v_{\alpha, \delta}$  is primitive by relating it to a construction earlier in the paper which is algebraically shown to be primitive. We use these primitive elements and their geometric construction in the following lemma:

**Lemma 3.1.** *Let  $\alpha, \delta \in \mathbb{Z}^+$  such that  $\gcd(\alpha, \delta) = 1$  and  $q|\delta$ . Then  $\pi_0(v_{\alpha, \delta}) = a^z b^\delta$  for some  $z \in \mathbb{Z}$  which depends only on  $\alpha \pmod{q}$ .*

**Proof.** Note that the  $x$ 's in  $v'_{\alpha, \delta}$  correspond to points  $(i, i\delta/\alpha)$  for  $0 < i < \alpha$ . Given each  $x$  in  $v'_{\alpha, \delta}$  we want to consider what it will take to move it to the front of the word. That is, we want to count the number of  $y$ 's that occur before each  $x$ . For the  $i$ th  $x$ , this is precisely the integer part of  $i\delta/\alpha$ . This is equal to  $(i\delta - r_i)/\alpha$  where  $0 \leq r_i < \alpha$  is the remainder when  $i\delta$  is divided by  $\alpha$ . In terms of the image of  $v'_{\alpha, \delta}$  under  $\pi$ , we only care about the number of  $y$ 's mod  $q$ . Since  $\gcd(\alpha, \delta) = 1$  and  $q|\delta$ , we have  $\gcd(q, \alpha) = 1$ . Thus there exists an  $\tilde{\alpha} \in \mathbb{Z}$  such that  $\alpha\tilde{\alpha} \equiv_q 1$ . It follows that  $(i\delta - r_i)/\alpha \equiv_q -\tilde{\alpha}r_i$  since  $q|\delta$ . Therefore, after commuting the  $i$ th  $a$  in the image of  $v'_{\alpha, \delta}$  to the front of

the word it becomes  $a^{\lambda^{-\tilde{\alpha}r_i}}$ . Thus the image of  $v'_{\alpha,\delta}$  under  $\pi$  is  $a^s b^{\delta-1}$  where

$$s = \sum_{i=1}^{\alpha-1} \lambda^{-\tilde{\alpha}r_i} = \sum_{i=1}^{\alpha-1} (\lambda^{-\tilde{\alpha}})^{r_i}.$$

Consider the list of remainders  $(r_1, r_2, \dots, r_{\alpha-1})$ . By the above considerations, this list completely determines the power of  $a$  in  $\pi(v'_{\alpha,\delta})$ . Since  $\gcd(\alpha, \delta) = 1$ ,  $[\delta] \in \mathbb{Z}/\alpha\mathbb{Z}$  is a generator. Furthermore, by definition  $[r_i] = i[\delta]$  in  $\mathbb{Z}/\alpha\mathbb{Z}$ . Thus up to reordering,  $(r_1, r_2, \dots, r_{\alpha-1}) = (1, 2, \dots, \alpha - 1)$ . As this is true for any choice of  $\delta$  meeting our requirements, for fixed  $\alpha$  the power of  $a$  in  $v'_{\alpha,\delta}$  and hence  $v_{\alpha,\delta}$  is independent of our choice of  $\delta$ .

Now fix  $\delta$ . If  $\alpha_2 = \alpha_1 + q$ , then we get two different lists of remainders. They are  $(1, 2, \dots, \alpha_1 - 1)$  and  $(1, 2, \dots, \alpha_2 - 1) = (1, 2, \dots, q, q + 1, q + 2, \dots, q + \alpha_1 - 1)$ . Let  $\lambda' := \lambda^{-\tilde{\alpha}_2}$ . Note that  $\alpha_1 \equiv_q \alpha_2 \implies \tilde{\alpha}_1 \equiv_q \tilde{\alpha}_2$ . Thus  $\lambda' = \lambda^{-\tilde{\alpha}_1}$ . Plugging this into our formula for the power of  $a$  in  $\pi(v'_{\alpha,\delta})$  and noting that  $(\lambda')^q \equiv_p 1$ , we get

$$\begin{aligned} \sum_{i=1}^{\alpha_2-1} (\lambda')^{r_i} &= \sum_{i=1}^q (\lambda')^{r_i} + \sum_{i=q+1}^{q+\alpha_1-1} (\lambda')^{r_i} \\ &\equiv_p \lambda' \left( \frac{1 - (\lambda')^q}{1 - \lambda'} \right) + \sum_{i=1}^{\alpha_1-1} (\lambda')^{r_i} \\ &\equiv_p \sum_{i=1}^{\alpha_1-1} (\lambda')^{r_i}. \end{aligned}$$

Thus  $\pi_0(v'_{\alpha_1,\delta}) = \pi_0(v'_{\alpha_2,\delta})$ . By induction, we see that  $\pi_0(v'_{\alpha,\delta})$  and hence  $\pi_0(v_{\alpha,\delta})$  only depends upon  $\alpha \pmod q$ . □

**3.2. Proof of Theorem 1.1.** With Proposition 1.2 and our lemmas, we are ready to prove Theorem 1.1.

**Proof of Theorem 1.1.** By Lemma 2.2, we may assume that  $\pi = \pi_0$ . Noting that  $Z(G) = 1$  so  $[G : Z(G)] = |G|$ , by Proposition 1.2 it suffices to show that  $\rho_0(\Gamma^+(G, \pi)) = \Gamma_1(q)$ . Since  $\rho_0(\Gamma^+(G, \pi)) \leq \rho_0(\Gamma^+(G^{\text{ab}}, \bar{\pi})) = \Gamma_1(q)$  where  $f \circ \pi = \bar{\pi}$  and  $f : G \rightarrow G^{\text{ab}}$  is the abelianization map, it remains to show  $\rho_0(\Gamma^+(G, \pi)) \geq \Gamma_1(q)$ .

Let  $A = \begin{bmatrix} \alpha & \beta \\ \delta & \epsilon \end{bmatrix} \in \Gamma_1(q)$ . Then let  $\varphi$  be the automorphism determined by

$$\begin{aligned} \varphi : F_2 &\rightarrow F_2 \\ x &\mapsto v_{\alpha,\delta} \\ y &\mapsto v_{\beta,\epsilon} \end{aligned}$$

By Theorem 1.2 of [OZ81], we have that  $v_{\alpha,\delta}$  and  $v_{\beta,\epsilon}$  generate  $F_2$ . Thus  $\varphi \in \text{Aut}^+(F_2)$ . Let  $\pi(v_{\beta,\epsilon}) = a^j b$ . It must be of this form since  $\epsilon \equiv_q 1$  and  $b$

has order  $q$ .

First assume  $\alpha, \delta > 0$ . Since  $p \nmid (\lambda - 1)$ , there exists an  $\ell \in \mathbb{Z}$  such that  $(\lambda - 1)\ell \equiv_p j$ . Then

$$\pi(x^\ell v_{\beta, \epsilon} x^{-\ell}) = a^\ell a^j b a^{-\ell} = a^\ell a^j a^{-\lambda \ell} b = a^{(1-\lambda)\ell + j} b = b$$

By Lemma 3.1, the  $a$  exponent of  $\pi(v_{\alpha, \delta})$  only depends upon  $\alpha \pmod q$ . But  $\alpha \equiv_q 1$  and  $v_{1, \delta} = xy^\delta$  by direct computation. Thus

$$\pi(x^\ell v_{\alpha, \delta} x^{-\ell}) = a^\ell a a^{-\ell} = a$$

This shows that  $c \circ \varphi \in \Gamma^+(G, \pi)$  where  $c$  is conjugation by  $x^\ell$ . Since  $\rho_0(c \circ \varphi) = A$  by construction, this shows  $A \in \rho_0(\Gamma^+(G, \pi))$ .

We now consider the case where  $\alpha$  and  $\delta$  are arbitrary. By the above argument,  $\begin{bmatrix} 1 & 0 \\ q & 1 \end{bmatrix} \in \rho_0(\Gamma^+(G, \pi))$ . Furthermore, for the correct choice of  $\ell$  as above, the automorphism

$$\begin{aligned} \psi : F_2 &\rightarrow F_2 \\ x &\mapsto x \\ y &\mapsto x^{\ell+1} y x^{-\ell} \end{aligned}$$

is in  $\Gamma^+(G, \pi)$ , and  $\rho_0(\psi) = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \in \rho_0(\Gamma^+(G, \pi))$ . For general  $\alpha, \delta$ , we may write  $A$  as a product of powers of these matrices and some  $A' = \begin{bmatrix} \alpha' & \beta' \\ \delta' & \epsilon' \end{bmatrix} \in \Gamma_1(q)$  with  $\alpha', \delta' > 0$ . This shows that  $A \in \rho_0(\Gamma^+(G, \pi))$ .  $\square$
