# Braided surfaces and their characteristic maps 

Louis Funar and Pablo G. Pagotto

#### Abstract

We show that branched coverings of surfaces of large enough genus arise as characteristic maps of braided surfaces that is, lift to embeddings in the product of the surface with $\mathbb{R}^{2}$. This result is nontrivial already for unramified coverings, in which case the lifting problem is well-known to reduce to the purely algebraic problem of factoring the monodromy map to the symmetric group $S_{n}$ through the braid group $B_{n}$. In our approach, this factorization is often achieved as a consequence of a stronger property: a factorization through a free group. In the reverse direction we show that any non-abelian surface group has infinitely many finite simple non-abelian groups quotients with characteristic kernels which do not contain any simple loop and hence the quotient maps do not factor through free groups. By a pullback construction, finite dimensional Hermitian representations of braid groups provide invariants for the braided surfaces. We show that the strong equivalence classes of braided surfaces are separated by such invariants if and only if they are profinitely separated.

## 1. Introduction

The question addressed in the present paper is the description of a particular case of 2-dimensional knots, called braided surfaces, up to fiber preserving isotopy.

[^0]Definition 1.1. A braided surface over some surface $\Sigma$ is an embedding of a surface $j: S \rightarrow \Sigma \times \mathbb{R}^{2}$, such that the composition

$$
S \stackrel{j}{\hookrightarrow} \Sigma \times \mathbb{R}^{2} \xrightarrow{p} \Sigma
$$

with the first factor projection $p$ is a branched covering. Throughout this paper we only consider locally flat PL embeddings $j$. The composition $p \circ j$ is called the characteristic map of the braided surface $S$.

Braided surfaces over the disk were first considered and studied by Viro, Rudolph (see [39]) and later extensively studied by Kamada ([19]). A comprehensive survey of the subject could be found in the monograph [20]. Braided surfaces over the torus were introduced more recently in [30].

Equivalence classes of braided surfaces are in one-to-one correspondence with a subset of the set of representations of the punctured surface group into the braid group up to conjugacy and mapping class group action. Our aim is to give some insight about the structure of such discrete representation varieties.

Definition 1.2. A map $S \rightarrow \Sigma$ between surfaces is called a 2-prem if it factors as above as $p \circ j$, where $j$ is an embedding and $p$ is the second factor projection $\Sigma \times \mathbb{R}^{2} \rightarrow \Sigma$.

Whether all generic smooth maps are 2-prems seems widely open. We refer to the article [29] of Melikhov for the state of the art on this question. Although branched coverings are not generic the question of whether they are 2-prems seems natural. Our first result gives an affirmative answer in the asymptotic range:

Theorem 1.3. There exists some $h_{n, m}$ such that any degree $n$ ramified covering of the closed orientable surface of genus $g \geq h_{n, m}$ with $m$ branch points occurs as a 2-prem.

The key ingredient is the description of the mapping class group orbits on the space of surface group representations onto a finite group in the stable range, i.e. for large genus $g$. This was done by Dunfield and Thurston (see [8]) in the closed case and by Catanese, Lönne and Perroni (see [6]) in the branched case. Their results establish the classification of these orbits by means of some versions of homological Schur invariants. Note that the bound $h_{n, m}$ is not explicit.

The genuine classification of these orbits seems much subtler, see [26] for a survey of this and related questions. Livingston provided ([24]) examples of distinct orbits with the same homological Schur invariants.

Definition 1.4. The homological Schur invariant of a surjective homomorphism $f: \pi_{1}(\Sigma) \rightarrow G$ of a closed orientable surface group onto a group $G$ is the image $s c(f) \in H_{2}(G)$ of the fundamental class $[\Sigma] \in H_{2}(\Sigma)$ by $f$. Recall that such a homomorphism $f: \pi_{1}(\Sigma) \rightarrow G$ is called elementary if it factors through a free group.

The null-homologous case, where the homological Schur invariant vanishes, corresponds to finding whether a surjective homomorphism $f: \pi_{1}(\Sigma) \rightarrow G$ of a closed surface group onto a finite group $G$ inducing a trivial map in 2homology is elementary. This amounts to estimating the minimal Heegaard genus for a 3-manifold group to which $f$ extends, problem which was recently considered by Liechti and Marché for tori (see [22]).

These questions arose in relation with the equivalence problem for epimorphisms of free groups onto non-abelian simple groups. Let $\mathbb{F}_{n}$ denote the free group on $n \geq 3$ generators and $\operatorname{Out}\left(\mathbb{F}_{n}\right)$ its outer automorphism group. Wiegold conjectured (see [26]) that for any finite simple non-abelian group $G$ the group $\operatorname{Out}\left(\mathbb{F}_{n}\right)$ acts transitively on the set of conjugacy classes of surjective homomorphisms $\mathbb{F}_{n} \rightarrow G$. A weaker statement which allows additional stabilizations is known to hold (see [28]). Also Gilman ([14]) and Evans ([10, 11]) proved that there exists a large orbit of $\operatorname{Out}\left(\mathbb{F}_{n}\right)$ on this set. In $[2,8]$ the authors proved that the action of the mapping class groups $\Gamma(\Sigma)$ on the set of conjugacy classes of surjective homomorphisms onto finite groups $G$ also has at least one large orbit.

Wiegold's conjecture implies that there is no isolated orbit, namely there is no finite simple quotient $G$ which is characteristic. Recall that a subgroup $H \subseteq$ $G$ is a characteristic subgroup of $G$ if it is invariant by all automorphisms of $G$. In this case $G / H$ is called a characteristic quotient of $G$.

In [13] one proved that there exist finite simple non-abelian quotients of surface groups which are characteristic, by using quantum representations. Conjugacy classes of surjective homomorphisms onto characteristic quotients of $\pi_{1}(\Sigma)$ are therefore isolated orbits for the action of the mapping class group, contrasting with large orbits from [2, 8]. An easy consequence is that all these quotient epimorphisms are non-elementary, so that the classification of mapping class group orbits fundamentally differs from the stable one. This improves previous work of Livingston ([24, 25]) and Pikaart ([37])(see Propositions 5.3 and 5.4):

Theorem 1.5. For any $g \geq 2$ there exist infinitely many simple non-abelian groups $G$ and surjective homomorphisms of the closed genus $g$ orientable surface onto $G$, such that the kernels are characteristic and do not contain any simple loop homotopy class. In particular, these homomorphisms are not elementary.

Remark 1.6. Given an embedding $G \subset S_{n}$, if the surjective homomorphism $\pi_{1}(\Sigma) \rightarrow G$ is elementary, then $f$ can be lifted to $\pi_{1}(\Sigma) \rightarrow B_{n}$. We don't know whether the non-elementary homomorphisms from Theorem 1.5 admit lifts to $B_{n}$, see also Remark 2.7.
Definition 1.7. Two braided surfaces $j_{i}: S \rightarrow \Sigma \times \mathbb{R}^{2}, i=0,1$ over $\Sigma$ are (Hurwitz) equivalent if there exists some ambient isotopy $h_{t}: \Sigma \times \mathbb{R}^{2} \rightarrow \Sigma \times \mathbb{R}^{2}$, $h_{0}=i d$ such that $h_{t}$ is fiber-preserving and $h_{1} \circ j_{0}=j_{1}$. Recall that $h_{t}$ is fiberpreserving if there exists a homeomorphism $\varphi_{t}: \Sigma \rightarrow \Sigma$ such that $p \circ h_{t}=\varphi_{t} \circ p$. There is no loss of generality to impose $\varphi_{t}$ to be an isotopy of $\Sigma$. Assume that
the branch loci of the branched coverings $j_{i} \circ p$ are the same finite set $B$. When $\varphi_{t}$ can be taken to be isotopy fixing pointwise the branch locus $B$, we say that the braided surfaces are strongly equivalent. These definitions extend naturally to the case when these surfaces have boundary by requiring isotopies to fix the boundary points of $j_{i}(S)$.

In the last part of this paper we show that finite dimensional Hermitian representations of braid groups provide invariants for the strong equivalence classes of braided surfaces, by a standard pullback construction (see section 7), called spherical functions. We then show that the topological information underlying the spherical functions is of profinite nature (see Theorem 7.7 for the general statement):

Theorem 1.8. Strong equivalence classes of braided surfaces are separated by some spherical function if and only if they are profinitely separated.

Acknowledgements. The authors are grateful to P. Bellingeri, G. Kuperberg, L. Liechti, M. Lönne, J. Marché, J.B. Meilhan, S. Melikhov, E. Samperton and E. Wagner for useful conversations and to the referees for pointing out several errors and incomplete arguments in the previous versions of this paper and improving the exposition.

## 2. Braided surfaces

Consider a braided surface over a closed orientable surface $\Sigma$, namely a locally flat PL embedding of a closed orientable surface $j: S \rightarrow \Sigma \times \mathbb{R}^{2}$, such that the composition $p \circ j$ is a branched covering. We might consider, more generally, that $S$ is embedded in a (orientable) plane bundle over $\Sigma$. However, the existence of nontrivial examples, for instance that some connected unramified covering of degree $>1$ arise as a characteristic map, implies that the plane bundle should be trivial (see [9]).

A degree $n$ branched covering $S \rightarrow \Sigma$ determines a homomorphism $f$ : $\pi_{1}(\Sigma \backslash B, *) \rightarrow S_{n}$, where $B$ is the branch locus of $F$, called a monodromy homomorphism. Choose small simple loops $\gamma_{i}$ each one encircling one branch point $b_{i}$ of $B$, which will be called peripheral loops or homotopy classes in the sequel.

The degree $n$ and branch locus $B$ of a braided surface $j: S \rightarrow \Sigma \times \mathbb{R}^{2}$ are, respectively, the degree and branch locus of its associated branched covering map $p \circ j$. Observe that the projection map

$$
\left.p\right|_{\left(\Sigma \times \mathbb{R}^{2}\right) \backslash j(S)}:\left(\Sigma \times \mathbb{R}^{2}\right) \backslash j(S) \rightarrow \Sigma
$$

restricts to a locally trivial fiber bundle over $\Sigma-B$. The monodromy of this locally trivial fiber bundle is then a homomorphism

$$
f: \pi_{1}(\Sigma \backslash B) \rightarrow B_{n}
$$

into the braid group $B_{n}$ on $n$-strands, which will be called the braid monodromy of the braided surface in the sequel.

Recall that two branched coverings $F_{1}, F_{2}: S \rightarrow \Sigma$ are equivalent if there are homeomorphisms $\Phi: S \rightarrow S$ and $\phi: \Sigma \rightarrow \Sigma$ such that $F_{1} \circ \Phi=\phi \circ F_{2}$. They are further strongly equivalent when there is some $\phi$ which is isotopic to the identity rel the branch locus.

Hurwitz proved that strong equivalence classes of branched coverings with given genus $g$ of $\Sigma, B$ and $n$, bijectively correspond to conjugacy classes of monodromy homomorphisms having nontrivial image on every peripheral loop. Denote by $\Gamma(\Sigma)$ the pure mapping class group of the possibly punctured surface $\Sigma$. Moreover, equivalence classes of branched coverings bijectively correspond to orbits of the mapping class group $\Gamma(\Sigma \backslash B)$ on the set of conjugacy classes of monodromy homomorphisms as above.

We will show that a similar result holds in the case of braided surfaces. Let $\gamma \subset \Sigma \backslash B$ be an embedded loop. Its preimage $\ell_{\gamma}=p^{-1}(\gamma) \cap j(S)$ is a link in the open solid torus $p^{-1}(\gamma) \simeq \gamma \times \mathbb{R}^{2}$. The link $\ell_{\gamma}$ is the link closure $\widehat{b}$ of a braid $b \in B_{n}$ within the solid torus, because the projection $\left.p\right|_{e_{\gamma}}: \ell_{\gamma} \rightarrow \gamma$ is an unramified covering. Note that the link $\ell_{\gamma}$ in the solid torus determines and is determined by the conjugacy class of $b$ in $B_{n}$.

If $\gamma$ were a peripheral loop, let us choose a bounding disk $\delta$ embedded in $\Sigma$, which contains a single point of $B$. Since $S$ is compact, we can assume that $j(S) \subset \Sigma \times D^{2}$, where $D^{2} \subset \mathbb{R}^{2}$ is a compact disk. Then $p^{-1}(\delta) \cap \Sigma \times D^{2} \simeq \delta \times D^{2}$ is a manifold with corners diffeomorphic (after rounding the corners) with the 4-disk $D^{4}$. In particular, the solid torus link $\ell_{\gamma}$ determines a link in $S^{3}$ by means of the embedding $e_{\gamma} \subset \gamma \times D^{2} \subset \partial D^{4}$.

Definition 2.1. A solid torus link $\ell \subset \gamma \times D^{2}$ is completely split if there exist disjoint disks $D_{i}^{2} \subset D^{2}$ such that each connected component of $L$ is contained within a solid torus $\gamma \times D_{i}^{2}$. The braid $b \in B_{n}$ is completely splittable if the corresponding link $\widehat{b} \subset \gamma \times D^{2}$ is completely split as a solid torus link and also trivial as a link in $S^{3}$. We denote by $\mathcal{A}_{n} \subset B_{n} \backslash\{1\}$ the set of completely splittable nontrivial braids.

If $\ell \subset \gamma \times D^{2}$ is a completely split unlink with components $\ell_{i}$, then choose points $x_{i} \in D_{i}^{2}$ and let $y$ be the single branch point belonging to $\operatorname{int}(\delta)$. Let $C\left(\ell_{i}\right)$ be the cone on $\ell_{i}$ with vertex $\left(y, x_{i}\right) \in \delta \times D^{2}$ and $C(\ell)$ be the union of $C\left(\ell_{i}\right)$. Since each component $\ell_{i}$ of $\ell$ is a trivial knot in $\partial\left(\delta \times D^{2}\right)$, the multi-cone $C(\ell)$ is the disjoint union of locally flat embedded disks in $\delta \times D^{2}$. Note that $C(\ell)$ is a braided surface over the disk $\delta$ with a single branch point $\{y\}$. By [20], Lemma 16.11) this is the unique braided surface over $\delta$ with branch point $\{y\}$ and boundary $\ell$.

Lemma 2.2. A braided surface $S$ of degree n over $\Sigma$ without branch points is determined up to equivalence rel boundary by its braid monodromy homomorphism $f: \pi_{1}(\Sigma) \rightarrow B_{n}$.

Proof. A homomorphism $f$ corresponds to a unique locally trivial fiber bundle over $\Sigma$ with fiber $D^{2} \backslash\left\{p_{1}, p_{2}, \ldots, p_{n}\right\}$ which is trivialized on the boundary $\partial D^{2}$
fiber bundle. One constructs the braided surface over a wedge of circles first and observe that it extends over the 2 -cell which produces the surface $\Sigma$, as $f$ is a group homomorphism.

Theorem 2.3. $A$ homomorphism $f: \pi_{1}(\Sigma \backslash B) \rightarrow B_{n}$ arises as the braid monodromy of some braided surface of degree $n$ with branch locus $B$ if and only if $f$ sends each peripheral loop $\gamma_{i}$ into a completely splittable nontrivial braid $f\left(\gamma_{i}\right) \in \mathcal{A}_{n} \subset B_{n}$. Moreover, a braided surface $S$ of degree $n$ over $\Sigma$ is determined up to strong equivalence by its braid monodromy $f: \pi_{1}(\Sigma \backslash B) \rightarrow B_{n}$.

Proof. Consider disjoint disks $\delta_{i}$ bounded by peripheral loops $\gamma_{i}$, for all branch points and let $X$ be their complement. Then $j(S) \cap p^{-1}\left(\delta_{i}\right)$ is a braided surface over the disk $\delta_{i}$. By ([20], Lemma 16.12) $j(S) \cap p^{-1}\left(\delta_{i}\right)$ has a braid monodromy homomorphism $f$ with $f\left(\gamma_{i}\right)$ completely splittable. This proves the necessity of our conditions.

Conversely, the multi-cone $C\left(\ell_{\gamma_{i}}\right)$ over the link $\ell_{\gamma_{i}}$ provides a braided surface over $\delta_{i}$. The homomorphism $f: \pi_{1}\left(\Sigma-\cup \delta_{i}\right) \rightarrow B_{n}$ provides by Lemma 2.2 a unique embedding $j: S^{\prime} \rightarrow \Sigma \times \mathbb{R}^{2}$ which has no branch points. We then glue together $S^{\prime}$ and the cones $C_{i}$ along their boundaries, in order to respect the projection map $p$. As the glued surface $S$ is unique, the braided surface is determined up to strong equivalence by $f$ (see also [19] and [20, Thm. 17.13]).

As an immediate consequence we have:
Corollary 2.4. The degree $n$ branched covering $S \rightarrow \Sigma$ with branch locus $B$ is the characteristic branched covering of a braided surface over $\Sigma$ if and only if its monodromy homomorphism $f: \pi_{1}(\Sigma \backslash B) \rightarrow S_{n}$ can be lifted to a homomorphism $F: \pi_{1}(\Sigma \backslash B) \rightarrow B_{n}$ such that $F$ sends peripheral loops into completely splittable nontrivial braids.

Proof. Theorem 2.3 yields a braided surface lifting some branched covering $S^{\prime} \rightarrow \Sigma$ of degree $n$, branch locus $B$ and the prescribed monodromy $f$. As the ramification degrees are determined by the cycle structure of the permutations corresponding to the peripheral loops, this branched covering can be identified with $S \rightarrow \Sigma$.

When $B=\emptyset$ we retrieve the following result of Hansen ( $[15,16]$ ):
Corollary 2.5. The degree n unramified covering $S \rightarrow \Sigma$ factors as the composition

$$
S \stackrel{j}{\hookrightarrow} \Sigma \times \mathbb{R}^{2} \xrightarrow{p} \Sigma
$$

of some embedding $j$ and the second factor projection $p$, if and only if its monodromy map $f: \pi_{1}(\Sigma) \rightarrow S_{n}$ lifts to a homomorphism $\pi_{1}(\Sigma) \rightarrow B_{n}$.

Another consequence is

Corollary 2.6. Degree $n$ braided surfaces on $\Sigma$ with branch locus B, up to strong equivalence rel boundary are in one-to-one correspondence with the set $M_{B_{n}}(\Sigma, B)$ of homomorphisms $\pi_{1}(\Sigma \backslash B) \rightarrow B_{n}$ sending peripheral loops into $\mathcal{A}_{n}$ modulo the conjugacy action by $B_{n}$. Furthermore, the classes of these braided surfaces up to equivalence rel boundary are in one-to-one with the set $\mathcal{M}_{B_{n}}(\Sigma, B)$ of orbits of the mapping class group $\Gamma(\Sigma \backslash B)$ action on $M_{B_{n}}(\Sigma, B)$ by left composition. In particular, braided surfaces provide a topological interpretation for the space of double cosets $B_{\infty} \backslash B_{\infty}^{k} / B_{\infty}$, studied by Pagotto in [32, 33].

Remark 2.7. Symmetric groups and braid groups form nested sequences $\subset S_{n} \subset$ $S_{n+1} \subset \cdots$ and $\subset B_{n} \subset B_{n+1} \subset \cdots$, where inclusions are induced by adding one more strand on the right. Inclusions are compatible with the projections $p_{n}$ : $B_{n} \rightarrow S_{n}$. We note that the answer to the lifting question for homomorphism $f: \pi_{1}(\Sigma \backslash B) \rightarrow S_{n}$ is independent on the chosen value for $n$. This follows from the existence of a group homomorphism $p_{n+1}^{-1}\left(S_{n}\right) \rightarrow B_{n}$ induced by the map removing the last strand from the right, which sends completely splittable braids into completely splittable braids.

Remark 2.8. The braided surfaces whose characteristic branched covering is a simple branched covering are analogous to achiral Lefschetz fibrations. The monodromy around a branch point is given by a band, namely a standard generator of the braid group or its inverse.

Remark 2.9. Recovering braided surfaces from their characteristic maps is just an instance of more general questions about compactifications of fibre bundles. There are examples of smooth maps between closed manifolds in specific dimensions having only finitely many critical points (see e.g. [12]). Characterizing the fibre bundle arising in the complementary of the critical locus and how they determine the original maps might have far-reaching implications.

## 3. Lifting homomorphisms and the proof of Theorem 1.3

3.1. The stable lifting problem. A basic problem in algebra and topology is, for a given surjective homomorphism $p: \tilde{G} \rightarrow G$, to characterize those group homomorphisms $f: J \rightarrow G$ which admit a lift to $\tilde{G}$, namely a homomor$\operatorname{phism} \varphi: J \rightarrow \tilde{G}$ such that $p \circ \varphi=f$. In the simplest case when $J$ is a free group any homomorphism is liftable. The next interesting case is $J=\pi_{1}\left(\Sigma_{g}\right)$, where $\Sigma_{g}$ denote the genus $g$ closed orientable surface and $g \geq 2$. The lifting question might appear under a slightly more general form, by requiring that $\left(\varphi\left(\gamma_{i}\right)\right)_{i=1, \ldots, m}=\left(c_{i}\right)_{i=1, \ldots, m} \in \widetilde{G}$, for a set of elements $\gamma_{i} \in J, c_{i} \in \widetilde{G}$.

Let $\Sigma^{\prime}$ be a closed orientable surface and $\Sigma$ a surface, possibly punctured. Denote by $\Sigma \sharp \Sigma^{\prime}$ the connected sum. There is a natural map $\Sigma \sharp \Sigma^{\prime} \rightarrow \Sigma$, called pinch which consists of crushing the complement of an open disk in $\Sigma^{\prime}$ to a point. The operation which replaces $\Sigma$ by $\Sigma \sharp \Sigma^{\prime}$ will be called a (genus) stabilization.

Although in general it seems difficult to lift homomorphisms $f$ (see [29, 34]) there is only a homological obstruction to lift $f$, if we allow the surface be stabilized, as it will be explained below.

Let $\Sigma_{h} \backslash B$ be a stabilization of the surface $\Sigma_{g} \backslash B, h \geq g+1$ and let $P$ : $\pi_{1}\left(\Sigma_{h} \backslash B\right) \rightarrow \pi_{1}\left(\Sigma_{g} \backslash B\right)$ be the homomorphism induced by the pinch map. If $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \xrightarrow{\rightarrow} G$ is a homomorphism, we call the composition $f \circ P$ a (genus) stabilization of $f$. We further say that $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ stably lifts along $p: \tilde{G} \rightarrow G$ if it has some stabilization $f^{\prime}=f \circ P: \pi_{1}\left(\Sigma_{h} \backslash B\right) \rightarrow G$ which lifts to $\tilde{G}$.
3.2. Lifting in the unramified case. We start with an outline of the proof of Theorem 1.3 in the unramified case. A homomorphism $\pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ corresponds to a homotopy class of based maps $f: \Sigma_{g} \rightarrow K(G, 1)$, thereby defining the Schur class $s c(f)=f_{*}\left(\left[\Sigma_{g}\right]\right) \in H_{2}(G)$.

Recall that two surjective homomorphisms $f, f^{\prime}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ are equivalent if there exists an automorphism $\Theta \in \operatorname{Aut}^{+}\left(\pi_{1}\left(\Sigma_{g}\right)\right)$ such that $f^{\prime}=f \circ \Theta^{-1}$. Here $\mathrm{Aut}^{+}\left(\pi_{1}\left(\Sigma_{g}\right)\right)$ is the group of automorphisms of the fundamental group which are induced by homeomorphisms preserving the orientation and fixing a point of the surface $\Sigma_{g}$. Alternatively, these are those automorphisms of $\pi_{1}\left(\Sigma_{g}\right)$ which act trivially on $H_{2}\left(\pi_{1}\left(\Sigma_{g}\right)\right)$. Now, Zimmermann ([43], see also [23]) proved that group epimorphisms have stabilizations which are equivalent if and only if their classes in the second homology agree.

This implies that an epimorphism stably lifts to $\tilde{G}$ if and only if its Schur class in $H_{2}(G)$ lies in the image of $H_{2}(\tilde{G})$. Indeed every class in $H_{2}(\tilde{G})$ is the Schur class of some homomorphism $\pi_{1}\left(\Sigma_{\tilde{g}}\right) \rightarrow \tilde{G}$, and moreover it is not hard to find a $\tilde{g}$ and such a homomorphism which is surjective (see Lemma 3.3).

Dunfield and Thurston (see [8]) improved this result when the group $G$ is finite. They showed that there exists $g(G)$ with the property that any two surjective homomorphisms $f, f^{\prime}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ with $g \geq g(G)$ having the same Schur class in $H_{2}(G)$ are already equivalent under the action of $\Gamma\left(\Sigma_{g, 1}\right) \times G$, where $G$ acts by inner automorphisms by right composition. The same argument as above shows that for large enough $g \geq g(G)$ a surjective homomorphism $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ lifts to $\tilde{G}$ if and only if $s c(f)$ lies in the image of $H_{2}(\tilde{G})$. Eventually, when $G \subseteq S_{n}$ and $\tilde{G}$ is the preimage of $G$ within the braid group $B_{n}$, one shows that $H_{2}(\tilde{G}) \rightarrow H_{2}(G)$ is surjective (see Lemma 3.8). This proves our claim.

The rest of this section is devoted to make this strategy work for the ramified case as well.
3.3. Schur invariants for punctured surfaces. We now describe a construction of homological Schur invariants for homomorphisms $\pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$. At first let $D^{2}$ be a disk embedded in $\Sigma_{g}$ containing the punctures $B=\left\{b_{1}, b_{2}, \ldots, b_{m}\right\}$ and $\gamma_{i}$ be a based loop encircling once the puncture $b_{i}$, so that $\gamma_{i}$ are pairwise disjoint except for their base-point. Identify then $\Sigma_{g} \backslash B$ with the boundary union of $\Sigma_{g} \backslash D^{2}$ and $D^{2} \backslash B$, so that there is a fixed system of curves $\gamma_{i}$ on $\Sigma_{g} \backslash B$.

Consider the surface with boundary $\Sigma$ obtained from $\Sigma_{g}$ after removing pairwise disjoint open small disks around each puncture $b_{i}$, namely replacing the
puncture $b_{i}$ with a boundary component $\mathbf{b}_{i}$. Let also $\Sigma^{\circ}$ be the result of cutting $\Sigma$ along the curves $\gamma_{i}$ and discarding the annuli bounded by $\mathbf{b}_{i}$ and $\gamma_{i}$.

Given elements $\mathbf{c}=\left(c_{i}\right)_{i=1, \ldots, m} \in G^{m}$ we represent them as homotopy classes of based oriented loops $l_{i}$ embedded within the space $K^{\prime}(G, 1)=K(G, 1) \times \mathbb{R}^{5}$, which are disjoint except for their base-point. Let also $L_{i}$ be disjoint embedded oriented loops in $K^{\prime}(G, 1)$ such that each pair $\ell_{i}$ and $L_{i}$ bounds an embedded annulus $A_{i}$ in $K^{\prime}(G, 1)$. Let $L_{\mathbf{c}}$ be the union of $L_{i}$.

A homomorphism $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ such that $f\left(\gamma_{i}\right)=c_{i} \in G$, for every $i$, provides a continuous based map $\phi: \Sigma^{\circ} \rightarrow K^{\prime}(G, 1)$, which is unique up to homotopy. Then $\phi\left(\gamma_{i}\right)$ is based homotopic to $\ell_{i}$. By adjoining these homotopies we can arrange that $\phi\left(\gamma_{i}\right)=\ell_{i}$. By gluing the annuli $A_{i}$ we obtain a based map $\phi: \Sigma \rightarrow K^{\prime}(G, 1)$ which sends $\partial \Sigma$ homeomorphically onto $L_{\mathbf{c}}$. Two based homotopies between $\phi\left(\gamma_{i}\right)$ and $\ell_{i}$ define a map from a 2 -sphere (with poles identified) into $K^{\prime}(G, 1)$ which must extend to the 3-disk, since $\pi_{2}\left(K^{\prime}(G, 1)\right)=$ 0 . This implies that

$$
\phi_{*}([\Sigma, \partial \Sigma]) \in H_{2}\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)
$$

is a well-defined homology class in the relative homology, independent on the various choices made in the construction.

Of course a homomorphism $f$ as above could only exist if $\prod_{i=1}^{m} c_{i}$ belongs to the commutator subgroup $[G, G]$, which we assume to be the case from now on.

Definition 3.1. Let $\mathbf{c}=\left(c_{i}\right)_{i=1, \ldots, m} \in G^{m}$ with $\prod_{i=1}^{m} c_{i} \in[G, G]$, and choose a system of curves $\gamma_{i}$ and a link $L_{\mathbf{c}}$ as above. We denote by $H_{2}(G ; \mathbf{c})$ the group $H_{2}\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)$ and say that $s c(f)=\phi_{*}([\Sigma, \partial \Sigma]) \in H_{2}(G ; \mathbf{c})$ is the Schur class of $f$.

From the exact sequence of the pair $\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)$ we derive the exact sequence:

$$
0 \rightarrow H_{2}(G) \rightarrow H_{2}(G, \mathbf{c}) \rightarrow \mathbb{Z}^{m} \rightarrow H_{1}(G)
$$

As the map $\phi$ is a degree one map on the circles $\gamma_{i}$, the image of $s c(f)$ in $H_{1}\left(L_{\mathbf{c}}\right)=\mathbb{Z}^{m}$ is $(1,1, \ldots, 1)$ and hence the rightmost map sends $(1,1, \ldots, 1) \in \mathbb{Z}^{m}$ into $0 \in H_{1}(G)$, by exactness. Classes in $H_{2}(G, \mathbf{c})$ whose image is $(1,1, \ldots, 1) \in$ $\mathbb{Z}^{m}$ will be called primitive.

A similar invariant, denoted $\varepsilon(f)$, was defined by Catanese, Lönne and Perroni in [5]. Our invariant $s c(f)$ is non-canonical, in the sense that it depends on the choice of the curves $\gamma_{i}$ and $L_{\mathbf{c}}$, while $\varepsilon(f)$ is canonical. The construction of $\varepsilon(f)$ proceeds as above, working with all possible values of $\mathbf{c}$ at once. The target group in [5] would naturally be $H_{2}\left(K(G, 1), K(G, 1)^{(1)}\right)$, where $K(G, 1)^{(1)}$ is the 1-skeleton of $K(G, 1)$. However, the classes so obtained in $H_{2}\left(K(G, 1), K(G, 1)^{(1)}\right)$ are only well-defined when we pass to a suitable quotient of it identifying classes of surfaces $\Sigma$ whose boundaries are only freely homotopic in $K(G, 1)$.

This equivalence relation between surface groups homomorphisms readily extends to surjective homomorphisms $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ with prescribed peripheral monodromy $f\left(\gamma_{i}\right)=c_{i}$, for $i=1, \ldots, m$. Then two homomorphisms
$f$ and $f^{\prime}$ as above are equivalent if there exists some $\Theta \in \operatorname{SAut}^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$ such that $f^{\prime}=f \circ \Theta^{-1}$. Here $\operatorname{SAut}{ }^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$ denotes the group of automorphisms of the group $\pi_{1}\left(\Sigma_{g} \backslash B\right)$ which are induced by homeomorphisms preserving the orientation of $\Sigma_{g} \backslash B$ fixing a point of the surface and preserving pointwise the punctures along with the peripheral monodromy, that is $f \circ \Theta^{-1}\left(\gamma_{i}\right)=c_{i}$, for $i=1, \ldots, m$. Observe that $\operatorname{SAut}^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$ contains the automorphisms of $\pi_{1}\left(\Sigma_{g} \backslash B\right)$ whose classes belongs to the subgroup $\Gamma\left(\Sigma_{g, 1}\right) \subset \Gamma\left(\Sigma_{g} \backslash B, *\right)$ of those mapping classes of homeomorphisms which are the identity on $D^{2} \backslash B \subset \Sigma_{g} \backslash B$. Then the Schur class $s c(f) \in H_{2}(G, \mathbf{c})$ of a homomorphism $f$ is invariant with respect to the left action by $\operatorname{SAut}^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$.

When $B=\emptyset$ the equivalence relation is compatible with the $G$-conjugacy. Consider the set

$$
M_{G}\left(\Sigma_{g}\right)=\operatorname{Hom}^{\mathrm{s}}\left(\pi_{1}\left(\Sigma_{g}\right), G\right) / G
$$

of $G$-conjugacy classes of surjective homomorphisms $f$. There is an obvious action of the mapping class group $\Gamma\left(\Sigma_{g}\right)$ on $M_{G}\left(\Sigma_{g}\right)$ by left composition. We say that $G$-conjugacy classes of homomorphisms are equivalent if they belong to the same $\Gamma\left(\Sigma_{g}\right)$-orbit. Conjugacy in $G$ acts trivially on $H_{2}(G)$. Livingston ([23], see also [43]) has proved that $G$-conjugacy classes of surjective homomorphisms are stably equivalent if and only if their classes in $\mathrm{H}_{2}(G)$ agree.

In the punctured case we fix an $m$-tuple $\mathbf{c} \in G^{m}$ and its conjugacy class with respect to the diagonal action:

$$
G \cdot \mathbf{c}=\left\{\left(a c_{i} a^{-1}\right)_{i=1, \cdots, m}, \mid a \in G\right\} \subset G^{m} .
$$

We then consider the set of surjective homomorphisms mod conjugacy:

$$
M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)=\left\{f \in \operatorname{Hom}^{s}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right), G\right) \mid\left(f\left(\gamma_{i}\right)\right)_{i=1, \cdots, m} \in G \cdot \mathbf{c}\right\} / G,
$$

where $\mathrm{Hom}^{\mathrm{s}}$ denotes the surjective homomorphism. The pure mapping class group $\Gamma\left(\Sigma_{g} \backslash B\right)$ (which fixes the punctures $b_{i}$ pointwise) has a left action on $\operatorname{Hom}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right), G\right) / G$ which keeps the subspace $M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)$ invariant. Conjugacy classes are said to be equivalent if they determine the same element in the orbit set:

$$
\mathcal{M}_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)=\Gamma\left(\Sigma_{g} \backslash B\right) \backslash M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right) .
$$

The conjugacy by $a \in G$ sends isomorphically $H_{2}(G ; \mathbf{c})$ onto $H_{2}\left(G, a \mathbf{c} a^{-1}\right)$, in particular $s c(f)$ does not descend to $M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)$. However we can identify those pairs of elements in the union of groups $H_{2}(G ; \mathbf{b})$, where $\mathbf{b} \in G \cdot \mathbf{c}$ which are related by some conjugacy isomorphism. The result is a quotient of $H_{2}(G ; \mathbf{c})$ which was explicitly described by Catanese, Lönne and Perroni in [5]. Moreover, the image of $s c(f)$ in this quotient group is the same as their $\varepsilon$ invariant which is defined on $M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)$.
3.4. Stable equivalence for punctured surfaces. The previous result of Livingston and Zimmermann on $G$-conjugacy classes was extended to the punctured case by Catanese, Lönne and Perroni in [6]. Specifically, the $G$-conjugacy
classes from $M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right)$ are stably equivalent if and only if their $\varepsilon$-invariants agree. There is a corresponding result for genuine homomorphisms, as follows:

Proposition 3.2. Surjective homomorphisms of surface groups with the same puncture set $B$ and boundary holonomy $\mathbf{c} \in G^{m}$ are stably equivalent if and only if their Schur classes in $\mathrm{H}_{2}(G, \mathbf{c})$ agree.

Proof. One can derive this from the corresponding stability result in [6]. However, there is a direct proof following the lines of the closed case (see [23]). First, the class $s c(f)$ is preserved by stabilizations. Further, if $\Omega_{n}(X, A)$ is the dimension $n$ orientable bordism group associated to the pair $(X, A)$ of CW complexes, then seminal work of Thom implies that the natural homomorphism

$$
\Omega_{n}(X, A) \rightarrow H_{n}(X, A)
$$

is an isomorphism if $n \leq 3$ and an epimorphism if $n \leq 6$ (see e.g. [40], Thm. IV.7.37). In particular, the classes in $H_{2}(G, p(\mathbf{c}))$ correspond to bordism classes of maps $f:(\Sigma, \partial \Sigma) \rightarrow\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)$.

The maps $f$ and $\left.f^{\prime}:\left(\Sigma^{\prime}, \partial \Sigma^{\prime}\right) \rightarrow\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)\right)$ are bordant if they extend to a 3-manifold. This means that that there exists a 3-manifold $M$ whose boundary splits as $\partial M=\partial_{+} M \cup \partial_{0} M \cup \partial_{-} M$, where $\partial_{+} M=\Sigma$ and $\partial_{-} M=\Sigma^{\prime}$, and a $\operatorname{map} F:\left(M, \partial_{0} M\right) \rightarrow\left(K^{\prime}(G, 1), L_{\mathbf{c}}\right)$, which restricts to $\partial_{ \pm} M$ to $f$ and $f^{\prime}$. We can assume that $\partial_{0} M$ is a trivial cobordism and moreover $F: \partial_{0} M \rightarrow L_{\mathbf{c}}$ is a product projection.

Take then a Heegaard surface $\left(\Sigma^{\prime \prime}, \partial \Sigma^{\prime \prime}\right)$ of the triad $\left(M, \partial_{+} M, \partial M_{-}\right)$, as in [4]. This means that $\partial \Sigma^{\prime \prime}$ is the union of core circles of $\partial_{0} M$ and $\Sigma^{\prime \prime}$ decomposes $M$ into two compression bodies $H$ and $H^{\prime}$. We can obtain such Heegaard decompositions by extending smoothly to $M$ a function which takes constant values on $\partial_{ \pm} M$ and perturb it away from the boundary to become Morse. Assuming that $\Sigma$ and $\Sigma^{\prime}$ are connected we obtain a Heegaard surface after attaching index one handles away from $\partial_{+} M$.

It follows that the map induced by $F_{*}$ on the image of $\pi_{1}\left(\Sigma^{\prime \prime}\right)$ within $\pi_{1}(M)$ is a common stabilization of the homomorphisms $f$ and $f^{\prime}$, up the the action of the gluing homeomorphism of the two compression bodies $H$ and $H^{\prime}$.

We now prove:
Lemma 3.3. Let $\tilde{G}$ be a finitely generated group, $\tilde{\mathbf{c}} \in \tilde{G}^{p}$ and $a \in H_{2}(\tilde{G}, \tilde{\mathbf{c}})$. Then there is a compact surface $\Sigma$ and a surjective homomorphism $\phi: \pi_{1}(\Sigma) \rightarrow \tilde{G}$ such that $\phi_{*}([\Sigma, \partial \Sigma])=a$ and $\left(f\left(\gamma_{i}\right)\right)_{i=1, \cdots, p}=\tilde{\mathbf{c}} \in \tilde{G}^{p}$.
Proof. Let first $a=0$ and $\tilde{\mathbf{c}}$ empty. For large enough $n$ there exists a surjective homomorphism $\psi: \mathbb{F}_{n} \rightarrow \tilde{G}$. Consider then $\phi_{0}=\psi \circ i_{*}$, where the homomorphism $i_{*}: \pi_{1}\left(\Sigma_{n}\right) \rightarrow \pi_{1}\left(H_{n}\right)=\mathbb{F}_{n}$ is induced by the inclusion $i$ of $\Sigma_{n}$ into the boundary of the genus $n$ handlebody $H_{n}$. Note that $i_{*}$ is a surjection. Then $\phi_{0_{*}}\left(\left[\Sigma_{n}\right]\right)=0$, as $\phi_{0}$ factors through a free group.

Let now $a \in H_{2}(\tilde{G}, \tilde{\mathbf{c}})$ be arbitrary. Pick a homomorphism $\psi_{a}: \pi_{1}\left(\Sigma_{m, p}\right) \rightarrow$ $\tilde{G}$ realizing the class $a$, so that $\left(\psi_{a}\left(\gamma_{i}\right)\right)_{i=1, \cdots, p}=\tilde{\mathbf{c}} \in \tilde{G}^{p}$. By crushing the genus
$n$ separating loop on $\Sigma_{n+m, p}$ to a point we obtain a surjective homomorphism $\pi: \pi_{1}\left(\Sigma_{n+m, p}\right) \rightarrow \pi_{1}\left(\Sigma_{n}\right) * \pi_{1}\left(\Sigma_{m, p}\right)$ onto the fundamental group of the join $\Sigma_{n} \vee \Sigma_{m, p}$. Consider further the homomorphism

$$
\psi_{0} * \psi_{a}: \pi_{1}\left(\Sigma_{n}\right) * \pi_{1}\left(\Sigma_{m, p}\right) \rightarrow \tilde{G} .
$$

Then the composition

$$
\phi_{a}: \pi_{1}\left(\Sigma_{n+m, p}\right) \rightarrow \tilde{G}, \quad \phi_{a}=\left(\psi_{0} * \psi_{a}\right) \circ \pi
$$

is surjective. Further, by Mayer-Vietoris we have

$$
\left.H_{2}\left(\Sigma_{n} \vee \Sigma_{m, p}, \partial \Sigma_{m, p}\right)\right)=H_{2}\left(\Sigma_{n}\right) \oplus H_{2}\left(\Sigma_{m, p}, \partial \Sigma_{m, p}\right)
$$

and

$$
\pi_{*}\left(\left[\Sigma_{n+m, p}, \partial \Sigma_{n+m, p}\right]\right)=\left(\left[\Sigma_{n}\right],\left[\Sigma_{m, p}, \partial \Sigma_{m, p}\right]\right) .
$$

This implies that $\phi_{a_{*}}\left(\left[\Sigma_{m+n, p}\right]\right)=a$. Thus $\phi_{a}$ satisfies our requirements.
Proposition 3.4. Consider $\tilde{\mathbf{c}} \in \tilde{G}^{p}$. The surjective homomorphism

$$
f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G
$$

stably lifts to a (surjective) homomorphism

$$
\varphi: \pi_{1}\left(\Sigma_{h} \backslash B\right) \rightarrow \tilde{G}
$$

satisfying the constraints $\varphi\left(\gamma_{i}\right)=\tilde{c_{i}}$, for $1 \leq i \leq p$, if and only if there exists a class $a \in H_{2}(\tilde{G}, \tilde{\mathbf{c}})$ such that

$$
p_{*}(a)=\operatorname{sc}(f)=f_{*}([\Sigma, \partial \Sigma]) \in H_{2}(G, p(\tilde{\mathbf{c}})) .
$$

Proof. If $\phi$ is the map provided by Lemma 3.3 above, then $p \circ \phi$ and $f$ are two surjective homomorphisms having the same Schur class. By the previous Proposition 3.2 they have equivalent stabilizations. This shows that $f$ is stably equivalent with a liftable homomorphism and hence stably liftable.
3.5. Finite target groups. In case when the group $G$ is finite there is an improvement of the stable equivalence of surface group epimorphisms, following the Dunfield-Thurston Theorem ([8], Thm.6.20) and we can state:

Proposition 3.5. Let $G$ be a finite group. There exists $g(G, m)$ with the property that any two surjective homomorphisms $f, f^{\prime}: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ with $g \geq g(G, m)$ and $f\left(\gamma_{i}\right)=f^{\prime}\left(\gamma_{i}\right)=c_{i} \in G$ having the same class in $H_{2}(G, \mathbf{c})$ are equivalent under the action of $\operatorname{SAut}^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$.
Proof. The proof from ([8] Thm. 6.20 and 6.23) extends without major modifications. In fact if $g>|G|$ any homomorphism $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ is a stabilization and this produces a surjective homomorphism induced by stabilization

$$
M_{G}\left(\Sigma_{g}, B, \mathbf{c}\right) \rightarrow M_{G}\left(\Sigma_{g+1}, B, \mathbf{c}\right) .
$$

It follows that the cardinal of the orbits set is eventually constant. On the other hand, by Proposition 3.2, the orbits set eventually injects into $\mathrm{H}_{2}(G, \mathbf{c})$.

Proposition 3.6. Let $G$ be a finite group $G, p: \tilde{G} \rightarrow G$ be a surjective homomorphism and $\mathbf{c} \in G^{m}$ such that $\prod_{i} c_{i} \in[G, G]$.
(1) There exist lifts $\tilde{\mathbf{c}} \in \tilde{G}^{m}$ such that $p(\tilde{\mathbf{c}})=\mathbf{c}$ and $\prod_{i} \tilde{c}_{i} \in[\tilde{G}, \tilde{G}]$.
(2) Given a lift $\tilde{\mathbf{c}}$ as in the previous item, there exists some $g(G, m, \tilde{G}, \tilde{\mathbf{c}})$ such that every surjective homomorphism $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow G$ with $f\left(\gamma_{i}\right)=$ $c_{i} \in G, g \geq g(G, m, \tilde{G}, \tilde{\mathbf{c}})$, for which there exists some class $a \in H_{2}(\tilde{G} ; \tilde{\mathbf{c}})$ satisfying

$$
\begin{gathered}
p_{*}(a)=\operatorname{sc}(f) \in H_{2}(G, \mathbf{c}) \\
\text { lifts to } \varphi: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow \tilde{G} \text { with the constraints }\left(\varphi\left(\gamma_{i}\right)\right)_{i=1, \cdots, m}=\tilde{\mathbf{c}} \in \tilde{G}^{m} .
\end{gathered}
$$

Proof. Let $K$ denote the kernel of the surjection $\tilde{G} \rightarrow G$. Choose any lift $\tilde{\mathbf{c}} \in$ $\tilde{G}^{m}$. Then the product of its components differs from a product of commutators by some element $k \in K$. We can correct this by replacing the lift $\tilde{c_{1}}$ by $k^{-1} \tilde{c_{1}}$. This proves the first claim.

Consider the finite set of all pairs ( $\mathbf{c}, s$ ), where $\mathbf{c} \in G^{m}$ is an $m$-tuple which admits a lift $\tilde{\mathbf{c}} \in \tilde{G}^{m}$ and some class $a_{\mathbf{c}} \in H_{2}(\tilde{G} ; \tilde{\mathbf{c}})$ projecting onto the primitive class $s \in H_{2}(G, \mathbf{c})$.

By Lemma 3.3 there exists a punctured surface $\Sigma_{k\left(a_{\mathrm{c}}\right)} \backslash B$ and a continuous map defined on the compact surface with boundary ( $\Sigma^{\prime}, \partial \Sigma^{\prime}$ ) which compactifies it, say $\left(\Sigma^{\prime}, \partial \Sigma^{\prime}\right) \rightarrow\left(K^{\prime}(\tilde{G}, 1), L_{\mathbf{c}}\right)$, which induces a surjective homomorphism $\phi: \pi_{1}\left(\Sigma_{k\left(a_{\mathrm{c}}\right)} \backslash B\right) \rightarrow \tilde{G}$ such that $\phi_{*}\left(\left[\Sigma^{\prime}, \partial \Sigma^{\prime}\right]\right)=a_{\mathrm{c}}$. Let then $g_{0}=g_{0}(G, m, \tilde{G}, \tilde{\mathbf{c}})$ be the maximum of all $k\left(a_{\mathbf{c}}\right)$.

If $g \geq g_{0}$ we stabilize $\phi$ to be defined on $\Sigma_{g} \backslash B$. Let then $\varphi=p \circ \phi$. Then $\varphi$ is a surjective homomorphism onto $G$ and

$$
\varphi_{*}\left(\left[\Sigma^{\prime}, \partial \Sigma^{\prime}\right]\right)=f_{*}([\Sigma, \partial \Sigma]) \in H_{2}(G, p(\tilde{\mathbf{c}}))
$$

Now, from Proposition 3.5. there exists some $g(G)$ such that for $g \geq g(G)$ any two surjective homomorphisms $\varphi$ and $f$ as above are equivalent up to the action of SAut ${ }^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$. We can take $g(G, m, \tilde{G}, \tilde{\mathbf{c}})=\max \left(g(G), g_{0}(G, m, \tilde{G}, \tilde{\mathbf{c}})\right)$. The action of SAut ${ }^{+}\left(\pi_{1}\left(\Sigma_{g} \backslash B\right)\right)$ preserves the set of homomorphisms $\pi_{1}\left(\Sigma_{g} \backslash\right.$ B) $\rightarrow G$ which admit a lift to $\tilde{G}$ with the given constraints, thereby proving our claim.

A directly related question is whether a surjective homomorphism $f: \pi_{1}\left(\Sigma_{g}\right)$ $\rightarrow G$ with vanishing Schur class factors through a free group $\mathbb{F}$, in which case of course it can be lifted along any epimorphism $p: \tilde{G} \rightarrow G$, for any group $\tilde{G}$. If this happens, the homomorphism $f$ will be called free, or elementary. As can be inferred from the previous results we have:

Proposition 3.7. Let $G$ be a finite group. Then there is some $g(G)$ such that for any $g \geq g(G)$ every surjective homomorphism $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ with $f_{*}\left(\left[\Sigma_{g}\right]\right)=$ $0 \in H_{2}(G)$ is elementary.
Proof. We can take $\widetilde{G}$ to be a fixed free group surjecting onto $G$ and use Proposition 3.6.

We now need some preliminary results concerning braid groups.
Lemma 3.8. Let $G \subseteq S_{n}$ be a finite group and $\tilde{G} \subset B_{n}$ be the preimage of $G$ by the projection homomorphism $p: B_{n} \rightarrow S_{n}$. Then the map $p_{*}: H_{2}(\tilde{G}) \rightarrow H_{2}(G)$ is surjective.

Proof. The kernel of $p$ is the pure braid group $P_{n}$ on $n$ strands. The five term exact sequence in homology reads:

$$
H_{2}(\tilde{G}) \rightarrow H_{2}(G) \rightarrow H_{1}\left(P_{n}\right)_{G} \rightarrow H_{1}(\tilde{G}) \rightarrow H_{1}(G) \rightarrow 0 .
$$

On one hand $H_{2}(G)$ is a torsion group, as $G$ is finite. Furthermore $H_{1}\left(P_{n}\right)$ is the free abelian group generated by the set $S(n)$ of classes $A_{i j}, 1 \leq i<j \leq n$ and the action of $S_{n}$ is

$$
\sigma \cdot A_{i j}=A_{\min (\sigma(i), \sigma(j)), \max (\sigma(i), \sigma(j))} .
$$

By ([3], II.2.ex.1) the module of co-invariants $H_{1}\left(P_{n}\right)_{G}=\mathbb{Z} S(n)_{G}$ is isomorphic to the free abelian group $\mathbb{Z}[S(n) / G]$. In particular any homomorphisms $H_{2}(G) \rightarrow H_{1}\left(P_{n}\right)_{G}$ must be trivial. Then the exact sequence above implies the claim.

### 3.6. Lifting permutations to completely splittable braids.

Lemma 3.9. Every m-tuple $\sigma \in S_{n}^{m}$ satisfying $\prod_{i} \sigma_{i} \in\left[S_{n}, S_{n}\right]$ has a lift $\tilde{\sigma} \in B_{n}^{m}$ with the properties:
(1) $\tilde{\sigma} \in \mathcal{A}_{n}^{m} \subset B_{n}^{m}$;
(2) $\prod_{i} \tilde{\sigma}_{i} \in\left[B_{n}, B_{n}\right]$;
(3) Suppose that $\left\{r_{1}, r_{2}, \ldots, r_{\nu}, t_{1}, t_{2}, \ldots, t_{\nu}\right\} \subseteq\{1,2, \ldots, m\}$ is a subset of the set of indices with the property $\sigma_{r_{s}}=\sigma_{t_{s}}^{-1}$, for $1 \leq s \leq \nu$. Then we can choose $\tilde{\sigma}_{i}$ such that additionally:

$$
\tilde{\sigma}_{r_{s}}=\tilde{\sigma}_{t_{s}}^{-1}, \text { for } 1 \leq s \leq \nu .
$$

Proof. Let $b_{i}, 1 \leq i \leq n-1$, denote the standard generators of the braid group $B_{n}$. Recall that the exponent sum $e: B_{n} \rightarrow \mathbb{Z}$ is the unique homomorphism taking values $e\left(b_{i}\right)=1$ on the standard generators. Set also $\tau_{j}$ for the transposition $(j, j+1)$ of $S_{n}$.

We first show that any permutation $\sigma$ has a lift $\tilde{\sigma} \in \mathcal{A}_{n}$, such that $e(\tilde{\sigma})=$ $\mu$, where $\mu$ is any prescribed element of $\{-1,1\}$, when $\sigma$ is odd and $\mu=0$, otherwise. This is obvious for $n=2$. We proceed by induction when $n>2$, by assuming the claim for $n-1$. Any $\sigma \in S_{n}$ which does not belong to $S_{n-1}$ can be written as $\sigma=\alpha \tau_{n-1} \beta$, where $\alpha, \beta \in S_{n-1}$. Pick-up some $\mu \in\{-1,0,1\}$ which is compatible with the parity of $\sigma$, as asked above. Choose an arbitrary lift $\tilde{\beta} \in$ $B_{n}$. By the induction hypothesis we can find a lift $\widetilde{\beta \alpha} \in \mathcal{A}_{n-1}$ with prescribed exponent $\operatorname{sum} \nu \in\{-1,0,1\}$, depending on the parity of the permutation $\beta \alpha \in$ $S_{n}$. We then define the lift:

$$
\tilde{\sigma}=\tilde{\beta}^{-1} \cdot \widetilde{\beta \alpha} \cdot \tau_{n-1}^{\delta} \cdot \tilde{\beta},
$$

where we set:

$$
\delta=\left\{\begin{array}{cl}
\mu, & \text { if } \mu \in\{-1,1\} \\
-\nu, & \text { if } \mu=0
\end{array}\right.
$$

Now $\tilde{\sigma}$ is conjugate to $\widetilde{\beta \alpha} \cdot \tau_{n-1}^{\delta}$ which is a stabilization of $\widetilde{\beta \alpha}$ and hence it has the same link closure as the latter. Therefore $\tilde{\sigma} \in \mathcal{A}_{n}$, proving the induction step and hence the claim. Moreover, we can take $\widetilde{\sigma^{-1}}=\tilde{\beta}^{-1} \cdot \tau_{n-1}^{-\delta} \cdot(\widetilde{\beta \alpha})^{-1} \cdot \tilde{\beta}$, as a lift of $\sigma^{-1}$, which still belongs to $\mathcal{A}_{n}$.

We can actually find explicit lifts $\tilde{\sigma}$ as follows. Recall that the half-braid $b_{i, j}$ is defined as:

$$
b_{i, j}= \begin{cases}b_{i} b_{i+1} \cdots b_{j-2} b_{j-1} b_{j-2}^{-1} \cdots b_{i+1}^{-1} b_{i}^{-1}, & i<j, \\ b_{i, j}=b_{j, i}^{-1}, & i>j\end{cases}
$$

To every permutation cycle $c=\left(i_{1}, i_{2}, \ldots, i_{k}\right) \in S_{n}$ and cycle signature map $\varepsilon:\left\{i_{1}, i_{2}, \ldots, i_{k-1}\right\} \rightarrow\{ \pm 1\}$, we associate a signed mikado braid, as follows:

$$
\beta(c, \varepsilon)=b_{i_{1}, i_{2}}^{\varepsilon\left(i_{1}\right)} b_{i_{2}, i_{3}}^{\varepsilon\left(i_{2}\right)} \cdots b_{i_{k-1}, i_{k}}^{\varepsilon\left(i_{k-1}\right)} \in B_{n} .
$$

Now, every permutation $\sigma \in S_{n}$ is the product of disjoint cycles, say $\sigma=$ $c_{1} c_{2} \cdots c_{s}$. Pick-up a cycle signature $\varepsilon_{i}$ for each cycle $c_{i}$. We then set:

$$
\beta\left(\sigma,\left(\varepsilon_{i}\right)\right)=\beta\left(c_{1}, \varepsilon_{1}\right) \beta\left(c_{2}, \varepsilon_{2}\right) \cdots \beta\left(c_{s}, \varepsilon_{s}\right) .
$$

Observe that $\beta(c, \varepsilon)$ and $\beta\left(c^{\prime}, \varepsilon^{\prime}\right)$ commute with each other if the cycles $c$ and $c^{\prime}$ are disjoint. This implies that $p\left(\beta\left(\sigma,\left(\varepsilon_{i}\right)\right)=\sigma\right.$.

Note that the closure of $\beta(c, \epsilon)$ is a trivial link, for any cycle $c$. In fact, we can assume up to a conjugacy, that the cycle $c$ has the form $(1,2, \ldots, k)$, so that up to a conjugacy in $B_{n}$ we have:

$$
\beta(c, \epsilon)=b_{1}^{\varepsilon(1)} b_{2}^{\varepsilon(2)} \cdots b_{k-1}^{\varepsilon(k-1)} \in B_{n} .
$$

Now we see that this is an iterated stabilization of a trivial braid and hence its closure is a trivial link, regardless of the cycle signature. Moreover, the closure of a product of such braids $\beta\left(c_{i}, \epsilon_{i}\right)$ associated to disjoint cycles $c_{i}$ is split, each cycle providing a single component of the link. Thus $\beta\left(\sigma,\left(\varepsilon_{i}\right)\right)$ is a completely split unlink.

We can always choose the cycle signature $\varepsilon$ of a given cycle $c$ such that $e(\beta(c, \epsilon))=0$, when $c$ has odd length and $e(\beta(c, \epsilon))=1$, otherwise. By changing the cycle signature above to its negative $-\varepsilon$ we can also find a cycle signature such that $e(\beta(c,-\epsilon))=-1$, if the length of $c$ is even. If $\sigma$ is the product of disjoint cycles $c_{i}$ we can find some cycle signatures $\varepsilon_{i}$ such that $e\left(\beta\left(\sigma,\left(\varepsilon_{i}\right)\right) \in\right.$ $\{-1,0,1\}$, by summing up factors with $e\left(\beta\left(c_{i}, \varepsilon_{i}\right) \in\{-1,0,1\}\right.$.

Let now $\sigma_{i} \in S_{n}$ be a collection of permutations such that $\prod_{i} \sigma_{i} \in\left[S_{n}, S_{n}\right]$. We then set $\left.\tilde{\sigma}_{i}=\beta\left(\sigma_{i}, \varepsilon_{i j}\right)\right)$ for suitable cycle signature maps $\varepsilon_{i j}$, such that $e\left(\beta\left(\sigma_{i},\left(\varepsilon_{i j}\right)\right) \in\{-1,0,1\}\right.$ and also $e\left(\prod_{i} \beta\left(\sigma_{i},\left(\varepsilon_{i j}\right)\right) \in\{-1,0,1\}\right.$.

If $\sigma_{r_{s}}=\sigma_{t_{s}}^{-1}$, then the decompositions into cycles correspond bijectively to each other. For each cycle $c_{r_{s} j}$ of length $k_{j}$ arising in the decomposition of $\sigma_{r_{s}}$
the cycle $c_{t_{s} j}=c_{r_{s} j}^{-1}$ appears in the decomposition of $\sigma_{t_{s}}^{-1}$. We then set:

$$
\varepsilon_{t_{s} j}(q)=\varepsilon_{r_{s} j}\left(k_{j}-q\right) .
$$

This implies that

$$
\beta\left(c_{t_{s},},\left(\varepsilon_{t_{s} j}\right)\right)=\beta\left(c_{r_{s} j},\left(\varepsilon_{r_{s} j}\right)\right)^{-1}
$$

and hence:

$$
\tilde{\sigma}_{r_{s}}=\beta\left(\sigma_{t_{s}},\left(\varepsilon_{t_{s}}\right)\right)=\beta\left(\sigma_{r_{s}},\left(\varepsilon_{r_{s} j}\right)\right)^{-1}=\tilde{\sigma}_{t_{s}}^{-1} .
$$

Since $\prod_{i} \sigma_{i}$ is an even permutation, $e\left(\prod_{i} \tilde{\sigma}_{i}\right)$ must be even and hence it must vanish, since it belongs to $\{-1,0,1\}$. This implies that $\prod_{i} \tilde{\sigma}_{i} \in\left[B_{n}, B_{n}\right]$, proving the claim.

Remark 3.10. We have a large freedom in the choice of lifts $\tilde{\sigma} \in \mathcal{A}_{n}$. Indeed any braid conjugate to $\beta\left(\sigma,\left(\varepsilon_{i}\right)\right)$ is in $\mathcal{A}_{n}$ and the corresponding product still belongs to the commutator subgroup of $B_{n}$.
3.7. End of proof of Theorem 1.3. We further have the following result, which along with Corollary 2.4 proves Theorem 1.3. Several arguments of the proof have essentially been discussed in [1].

Theorem 3.11. There exists some $h_{n, m}$ such that if $g \geq h_{n, m}$, then every homomorphism $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow S_{n}$, admits a lift $\varphi: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow B_{n}$ satisfying $\varphi\left(\gamma_{i}\right) \in \mathcal{A}_{n}$.

The case $n=3$ and $B=\emptyset$ was solved in [17].
Proof. The group $S_{n}$ is generated by two elements $a$ and $b$, for instance a $n$ cycle and a transposition. Set $B^{\prime}$ for the result of adding 4 more points $p_{m+1}$, $p_{m+2}, p_{m+3}$, and $p_{m+4}$ to $B$. There is a natural surjection $\pi_{1}\left(\Sigma_{g} \backslash B^{\prime}\right) \rightarrow \pi_{1}\left(\Sigma_{g} \backslash B\right)$ which corresponds to removing the extra punctures. Define the lift $f^{\prime}: \pi_{1}\left(\Sigma_{g} \backslash\right.$ $\left.B^{\prime}\right) \rightarrow S_{n}$ of $f$ by asking that the monodromy $\sigma_{m+i}$ around a loop encircling once counterclockwise $p_{m+i}$, for $1 \leq i \leq 4$ be $a, a^{-1}, b$ and $b^{-1}$, respectively. By construction $f^{\prime}$ is a surjective homomorphism onto $S_{n}$.

By Lemma 3.9 we can choose for each $(m+4)$-tuple $\sigma \in S_{n}^{m+4}$ some lift $\tilde{\sigma} \in \mathcal{A}_{n}^{m+4} \subset B_{n}^{m+4}$ with $\prod_{i} \tilde{c}_{i} \in\left[B_{n}, B_{n}\right]$ and $\tilde{\sigma}_{m+1} \tilde{\sigma}_{m+2}=1, \tilde{\sigma}_{m+3} \tilde{\sigma}_{m+4}=1$. Let $h_{n, m}$ be the maximum of $g\left(S_{n}, m+4, B_{n}, \tilde{\sigma}\right)$, over all $\sigma \in S_{n}^{m+4}$.

We claim that we can lift $f^{\prime}$ to $B_{n}$ with the constraints $\tilde{\sigma} \in B_{n}^{m+4}$. By Proposition 3.6, it suffices to prove that the homomorphism $p_{*}: H_{2}\left(B_{n}, \tilde{\mathbf{c}}\right) \rightarrow H_{2}\left(S_{n}, \mathbf{c}\right)$ surjects onto the primitive classes. We have a commutative diagram:

$$
\begin{array}{rlrllllll}
0 & \rightarrow & H_{2}\left(B_{n}\right) & \rightarrow & H_{2}\left(B_{n}, \tilde{\mathbf{c}}\right) & \rightarrow & \mathbb{Z}^{m+4} & \rightarrow & H_{1}\left(B_{n}\right) \\
\downarrow & \rightarrow 0 \\
& & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & H_{2}\left(S_{n}\right) & \rightarrow & H_{2}\left(S_{n}, \mathbf{c}\right) & \rightarrow & \mathbb{Z}^{m+4} & \rightarrow & H_{1}\left(S_{n}\right)
\end{array} \rightarrow 0,0,
$$

where the rightmost vertical arrow is the homomorphism induced by the projection $H_{1}\left(B_{n}\right) \rightarrow H_{1}\left(S_{n}\right)$, which is surjective. Note that the third vertical arrow is $H_{1}\left(L_{\tilde{\mathbf{c}}}\right) \rightarrow H_{1}\left(L_{\mathbf{c}}\right)$, which is an isomorphism. Then the five-lemma reduces the surjectivity claim to the surjectivity of $p_{*}: H_{2}\left(B_{n}\right) \rightarrow H_{2}\left(S_{n}\right)$, which was proved in Lemma 3.8.

Therefore $f^{\prime}$ lifts to a homomorphism $\varphi^{\prime}: \pi_{1}\left(\Sigma_{g} \backslash B^{\prime}\right) \rightarrow B_{n}$. By removing from $\Sigma_{g} \backslash B$ two disks containing the pairs $p_{m+1}, p_{m+2}$ and $p_{m+3}, p_{m+4}$ respectively, we obtain a surface with boundary, whose fundamental group injects into $\pi_{1}\left(\Sigma_{g} \backslash B^{\prime}\right)$. The homomorphism $\varphi^{\prime}$ takes trivial values on the loops around each of the two holes. Therefore $\varphi^{\prime}$ induces a homomorphism of the fundamental group of the surface obtained by capping off the boundary components by disks, namely a homomorphism $\varphi: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow B_{n}$. This is the desired lift for $f$.

## 4. Thickness of elementary surface group homomorphisms

4.1. Elementary homomorphisms and 3-manifolds. For the sake of simplicity, we stick in this section to the unramified case $B=\emptyset$. Let $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow$ $G$ be a surjective homomorphism. Assume that $f_{*}\left(\left[\Sigma_{g}\right]\right)=0 \in H_{2}(G)$. Then there exists some 3-manifold $M^{3}$ with boundary $\Sigma_{g}$ such that $f$ extends to $F$ : $\pi_{1}\left(M^{3}\right) \rightarrow G$ (see the proof of Propositions 3.2 and 4.2).

Definition 4.1. The thickness $t(f)$ of the surjective homomorphism $f: \pi_{1}\left(\Sigma_{g}\right)$ $\rightarrow G$ with $s c(f)=0$ is the smallest value of $n$ for which there exists a 3-manifold $M^{3}$ with boundary $\Sigma_{g}$ and Heegaard genus $g+n$ such that $f$ extends to $F$ : $\pi_{1}\left(M^{3}\right) \rightarrow G$.

Other meaningful versions might be the rank of the homology or the rank of $\pi_{1}\left(M^{3}\right)$, the hyperbolic volume (when $g=1$ ) of $M^{3}$ or any other complexity function on 3-manifolds.

This situation generalizes the case of the commutator width of elements in $[G, G]$. On the other hand it is an analog of Thurston's norm on the homology $H_{2}(M)$ of a 3-manifold.

Proposition 4.2. Let $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ be a homomorphism satisfying $f_{*}\left(\left[\Sigma_{g}\right]\right)=$ $0 \in H_{2}(G)$. The minimal genus $h$ for which there exists a stabilization $f^{\prime}$ : $\pi_{1}\left(\Sigma_{h}\right) \rightarrow G$ which is elementary equals the minimal Heegaard genus a 3-manifold $M^{3}$ with boundary $\Sigma_{g}$ such that $f$ extends to a homomorphism $\pi_{1}\left(M^{3}\right) \rightarrow G$.

Proof. The arguments come from Livingston's proof ([23, 8]) of the stable equivalence of homomorphisms. Observe that there is a map $F: \Sigma_{g} \rightarrow B G$ inducing $f$ at the fundamental group level. Our assumptions and Thom's solution to the Steenrod realization problem implies that there is some 3-manifold $M^{3}$ with boundary $\Sigma_{g}$ such that $F$ extends to a map still denoted by the same letter $F: M^{3} \rightarrow B G$. It follows that $f$ factors as the composition

$$
\pi_{1}\left(\Sigma_{g}\right) \rightarrow \pi_{1}\left(M^{3}\right) \xrightarrow{F_{*}} G,
$$

where $\pi_{1}\left(\Sigma_{g}\right) \rightarrow \pi_{1}\left(M^{3}\right)$ is the homomorphism induced by the inclusion.
Let $\Sigma_{k}$ be a Heegaard surface in $M^{3}$, bounding a handlebody $H_{k}$ of genus $k$ on one side and a compression body $H_{k, g}$ on the other side. Recall that a compression body $H_{k, g}$ is a compact orientable irreducible 3-manifold obtained
from $\Sigma_{k} \times[0,1]$ by adding 2-handles with disjoint attaching curves, so that $\pi_{1}\left(\Sigma_{k}\right) \rightarrow \pi_{1}\left(H_{k, g}\right)$ is surjective. Alternatively we can see $H_{k, g}$ as the result of adding to $\Sigma_{g} \times[0,1]$ a number of 1-handles, so that $\pi_{1}\left(H_{k, g}\right)=\pi_{1}\left(\Sigma_{g}\right) * \mathbb{F}_{k-g}$. We then have $\pi_{1}\left(M^{3}\right)=\pi_{1}\left(H_{k}\right) *_{\pi_{1}\left(\Sigma_{k}\right)} \pi_{1}\left(H_{k, g}\right)$ where all homomorphisms are induced by the inclusions.

Observe that $f$ is given by the composition:

$$
\pi_{1}\left(\Sigma_{g}\right) \rightarrow \pi_{1}\left(H_{k, g}\right) \rightarrow \pi_{1}\left(M^{3}\right) \xrightarrow{F_{*}} G,
$$

where the first two arrows are inclusion induced homomorphisms. Consider now the homomorphism $f^{\prime}$ defined by the composition

$$
\pi_{1}\left(\Sigma_{k}\right) \rightarrow \pi_{1}\left(H_{k, g}\right) \rightarrow \pi_{1}\left(M^{3}\right) \xrightarrow{F_{*}} G,
$$

where the first two arrows are inclusion induced homomorphism. Since $F_{*}$ extends $f$, it follows that $f^{\prime}$ is a stabilization of $f$ (see also [8] section 6.15). On the other hand $f^{\prime}$ factors through the free group $\pi_{1}\left(H_{k}\right)$. It follows that $h$ is bounded by the Heegaard genus, $h \leq k$.

Conversely, let $f^{\prime}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow G$ be a stabilization of $f$ which factors through a free group $\mathbb{F}$, namely we can write it as $f^{\prime}=q^{\prime} \circ \rho$, where $q^{\prime}: \mathbb{F} \rightarrow G$ and $\rho: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \mathbb{F}$.

Recall the following lemma due to Zieschang, Stallings and Jaco (see [42], [21, Lemma 3.2]) in the form presented by Liechti and Marché ([22], Lemma 3.5):

Lemma 4.3. Let $\Sigma_{h}$ be a surface bounding a handlebody $H_{h}$ and $\mathbb{F}$ a free group. Then any homomorphism $\rho: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \mathbb{F}$ factors as $q \circ i_{*} \circ \phi_{*}$, where $\phi_{*}$ is an automorphism of $\pi_{1}\left(\Sigma_{h}\right)$ preserving the orientation, $i: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \pi_{1}\left(H_{h}\right)$ is the inclusion and $q: \pi_{1}\left(H_{h}\right) \rightarrow \mathbb{F}$ is a homomorphism.

Write then $\rho=q \circ i_{*} \circ \phi_{*}$ as in Lemma 4.3 and define the manifold $M^{3}=$ $H_{h} \cup_{\phi} H_{h, g}$, where the gluing homeomorphism $\phi$ induces the automorphism $\phi_{*}$. It then follows that $f^{\prime}$ factors through $\pi_{1}\left(M^{3}\right)=\pi_{1}\left(H_{h}\right) *_{\pi_{1}\left(\Sigma_{h}\right)} \pi_{1}\left(H_{h, g}\right)$. Since $\Sigma_{h}$ is a Heegaard surface in $M^{3}$ we derive that $k \leq h$.

Corollary 4.4. There is some $h_{n}$ such that whenever $g \geq h_{n}$ and $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow$ $G \subseteq S_{n}$ is a homomorphism with $f_{*}\left(\left[\Sigma_{g}\right]\right)=0 \in H_{2}(G)$, then $f$ is equivalent to a homomorphism which factors through $\pi_{1}\left(H_{g}\right)$.
4.2. Expressing thickness algebraically. The next result aims at providing an algebraic formula for $t(f)$, similar to Hopf's formula for the second homology. Consider a standard presentation of the group $\pi_{1}\left(\Sigma_{g}\right)$ using the generators system $\left\{a_{i}, b_{i}\right\}_{i \in\{1,2, \ldots, g\}}$ of the form:

$$
\pi_{1}\left(\Sigma_{g}\right)=\left\langle\left\{a_{i}, b_{i}\right\}_{i \in\{1,2, \ldots, g\}} \mid \prod_{i=1}^{g}\left[a_{i}, b_{i}\right]=1\right\rangle .
$$

Then one identifies a homomorphism $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ with a labeled set $S=$ $\left\{\alpha_{i}=f\left(a_{i}\right), \beta_{i}=f\left(b_{i}\right)\right\}_{i \in\{1,2, \ldots, g\}}$ of elements of $G$ satisfying the condition:

$$
\begin{equation*}
\prod_{i=1}^{g}\left[\alpha_{i}, \beta_{i}\right]=1 \in G \tag{4.1}
\end{equation*}
$$

Let $G=\mathbb{F} / R$ be a presentation of the group $G$, where $\mathbb{F}$ is a free group and $R$ the normal subgroup generated by the relators. For every labeled set $\tilde{S}=$ $\left\{\left(\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right)_{i \in\{1,2, \ldots, g\}}\right.$ of lifts of $S$ to $\mathbb{F}$ we set:

$$
\begin{align*}
& \operatorname{ocl}(\tilde{S})=\min \left\{n \mid \text { there exist } f_{j} \in \mathbb{F}, r_{j} \in R, j=1,2, \ldots, n\right. \text { with }  \tag{4.2}\\
& \left.\qquad \prod_{i=1}^{g}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right]=\prod_{j=1}^{n}\left[r_{j}, f_{j}\right]\right\} .
\end{align*}
$$

Note that such $n$ exists. Indeed the Hopf formula provides us with an isomorphism

$$
H_{2}(G)=\frac{[\mathbb{F}, \mathbb{F}] \cap R}{[\mathbb{F}, R]} .
$$

Under this identification the $f_{*}\left(\left[\Sigma_{g}\right]\right)$ is represented by the class of the element $\prod_{i=1}^{g}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right] \in[\mathbb{F}, \mathbb{F}] \cap R$. As $f_{*}\left(\left[\Sigma_{g}\right]\right)$ vanishes by our assumptions $\prod_{i=1}^{g}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right] \in$ $[\mathbb{F}, R]$.

Eventually we define:

$$
\begin{equation*}
o c l(f)=\min \{o c l(\tilde{S}) \mid \tilde{S} \text { lifts } S\} . \tag{4.3}
\end{equation*}
$$

We then have the following:
Proposition 4.5. The minimal number of stabilizations needed for making $f$ elementary is ocl $(f)-g$.

Proof. By Proposition 4.2 the minimal $h=g+n$ which appears above is the minimal Heegaard genus of a manifold $M^{3}$ with boundary $\Sigma_{g}$ such that $f$ extends to some homomorphism $F_{*}: \pi_{1}\left(M^{3}\right) \rightarrow G$. It remains to prove that the smallest Heegaard genus coincides with ocl $(f)$. The proof goes similarly with that given by Liechti-Marché [22] for the case of a bordant torus.

Let $\Sigma_{h}$ a Heegaard surface in $M^{3}$. Take a standard system of generators of $\pi_{1}\left(\Sigma_{h}\right)$ of the form $\left\{a_{j}, b_{j}\right\}_{j=1, \ldots, h}$ such that all $b_{j}$ bound disks in the handlebody $H_{h}$. By adjoining 2-handles to $\Sigma_{h} \times[0,1]$ along $b_{j} \times\{0\}$, for all $j \notin\{1,2, \ldots, g\}$, we obtain a compression body $H_{h, g}$ and we can write $M^{3}=H_{h, g} \cup_{\phi} \overline{H_{h}}$, for some gluing homeomorphism $\phi$. We have then surjective homomorphisms $\pi_{1}\left(\Sigma_{h}\right) \rightarrow$ $\pi_{1}\left(H_{h}\right)$ and $\pi_{1}\left(\Sigma_{h}\right) \rightarrow \pi_{1}\left(H_{h, g}\right)$, while $\pi_{1}\left(M^{3}\right)=\pi_{1}\left(H_{h, g}\right) *_{1}\left(\Sigma_{h}\right) \pi_{1}\left(H_{h}\right)$.

Denote by $\theta_{*}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \pi_{1}\left(M^{3}\right)$ the inclusion induced homomorphism. We observed in the proof of Proposition 4.2 above that $F_{*} \circ \theta_{*}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow G$ is a stabilization of $f$. Its key property is that

$$
F_{*} \circ \theta_{*}\left(b_{i}\right)=1 \text {, if } i \notin\{1,2, \ldots, g\} .
$$

The homomorphism $\theta$ factors through the free group $\pi_{1}\left(H_{h}\right)$. Therefore $F_{*} \circ \theta_{*}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow G$ lifts to a homomorphism $\tilde{f}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \mathbb{F}$. Consider the images $\tilde{\alpha}_{j}=\tilde{f} \circ i_{*}\left(a_{j}\right), \tilde{b}_{j}=\tilde{f} \circ i_{*}\left(b_{j}\right)$ of the generators above into $\mathbb{F}$. As $\tilde{f} \circ i_{*}$ is a homomorphism, we have the relation:

$$
\begin{equation*}
\prod_{i=1}^{g}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right]=\prod_{i=g+1}^{h}\left[\tilde{\beta}_{i}, \tilde{\alpha}_{i}\right] . \tag{4.4}
\end{equation*}
$$

As $\tilde{\beta}_{i} \in R$, we derive that

$$
\begin{equation*}
\operatorname{ocl}(f)+g \leq h \tag{4.5}
\end{equation*}
$$

Conversely, if we have elements $\tilde{\alpha}_{j}, \tilde{\beta}_{j}$ satisfying equation (4.4), then we can define a homomorphism $\tilde{f}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow \mathbb{F}$, by $\tilde{f}\left(\alpha_{j}\right)=\tilde{\alpha}_{j}, \tilde{f}\left(\beta_{j}\right)=\tilde{\beta}_{j}, 1 \leq j \leq$ $h$. By Lemma 4.3 such a homomorphism factors through $\pi_{1}\left(H_{h}\right)$, namely is a composition

$$
\tilde{f}=q \circ i_{*} \circ \phi_{*}^{-1},
$$

where $i_{*}$ is as above, $\phi_{*}$ is an automorphism of $\pi_{1}\left(\Sigma_{h}\right)$ and $q: \pi_{1}\left(H_{h}\right) \rightarrow \mathbb{F}$ is some homomorphism.

Let $f^{\prime}: \pi_{1}\left(\Sigma_{h}\right) \rightarrow G$ be the composition of the projection $\mathbb{F} \rightarrow G$ with $\tilde{f}$. Then $f^{\prime} \circ \phi_{*}\left(b_{i}\right)=1$, for $i=1,2, \ldots, h$. On the other hand, as $\tilde{\beta}_{j} \in R$, for $j>g, f^{\prime}$ factors also through $\pi_{1}\left(H_{h, g}\right)$. This implies that $f^{\prime}$ extends to a homomorphism $F_{*}: \pi_{1}\left(M^{3}\right) \rightarrow G$, where $M^{3}=H_{h, g} \cup_{\phi} \overline{H_{h}}$. Eventually, note that the restriction of $F_{*}$ to the image of $\pi_{1}\left(\Sigma_{g}\right)$ within $\pi_{1}\left(M^{3}\right)$ is $f$. We constructed an extension of $f$ to a 3-manifold of Heegaard genus at most $h$ and thus we proved the reverse inequality

$$
\begin{equation*}
\operatorname{ocl}(f)+g \geq h \tag{4.6}
\end{equation*}
$$

Remark 4.6. Consider two surjective homomorphisms $f_{j}: \pi_{1}\left(\Sigma_{g_{j}}\right) \rightarrow G$. We know that $f_{j}$ are stably equivalent if and only

$$
f_{1_{*}}\left[\Sigma_{1}\right]=f_{2_{*}}\left[\Sigma_{2}\right] \in H_{2}(G) .
$$

If $S_{j}=\left\{\alpha_{i}, \beta_{i}\right\}_{i \in I_{j}}$ are images of generators of $\pi_{1}\left(\Sigma_{j}\right)$ by $f_{j}$ and $\tilde{S}_{j}=\left\{\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right\}_{i \in I_{j}}$ are lifts to $\mathbb{F}$, we can define

$$
\begin{aligned}
& \operatorname{ocl}^{s}\left(\tilde{S}_{1}, \tilde{S}_{2}\right)=\min \left\{n \mid \text { there exist } f_{j}, f_{j}^{\prime} \in \mathbb{F}, r_{j}, r_{j}^{\prime} \in R,\right. \text { such that : } \\
& \left.\qquad \prod_{i \in I_{1}}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right] \prod_{j=1}^{n-g_{1}}\left[r_{j}, f_{j}\right]=\prod_{i \in I_{2}}\left[\tilde{\alpha}_{i}, \tilde{\beta}_{i}\right] \prod_{j=1}^{n-g_{2}}\left[r_{j}^{\prime}, f_{j}^{\prime}\right]\right\} .
\end{aligned}
$$

Eventually we set:

$$
\operatorname{ocl}^{s}\left(f_{1}, f_{2}\right)=\min \left\{\operatorname{ocl}\left(\tilde{S}_{1}, \tilde{S}_{2}\right) \mid \tilde{S}_{j} \text { lifts } S_{j}\right\}
$$

If $f_{1}$ and $f_{2}$ are stably equivalent, then $\operatorname{ocl}^{s}\left(f_{1}, f_{2}\right)$ equals the minimal genus of a Heegaard splitting separating the boundaries of a 3-manifold to which $f_{j}$
extend and also the minimal number of stabilizations yielding equivalent representations in $G$. The proof is identical.
Remark 4.7. The branched surface case of homomorphisms $f: \pi_{1}\left(\Sigma_{g} \backslash B\right) \rightarrow$ $G$ with prescribed images of peripheral loops follows directly from the closed surface treated above, without essential modifications.

## 5. Nontrivial thickness and proof of Theorem 1.5

5.1. Finite simple non-abelian characteristic quotients. In [13] the authors proved that the obvious extension of Wiegold's conjecture to surface groups does not hold.

Let $\Sigma_{g}^{1}$ denote the once punctured closed orientable surface of genus $g$. TQFTs provide the so-called quantum representations of punctured mapping class groups

$$
\rho_{p}: \Gamma\left(\Sigma_{\mathrm{g}}^{1}\right) \rightarrow P \mathbb{G}_{p},
$$

for prime $p \equiv 3(\bmod 4)$, into the integral points of a projective pseudo-unitary group $P \mathbb{G}_{p}$ defined over $\mathbb{Q}$. It is proved in [13] that for large enough $p$ (or $p<$ 100) the restriction to $\rho_{p}\left(\pi_{1}\left(\Sigma_{g}\right)\right)$ is a Zariski dense subgroup of $P \mathbb{G}_{p}$. By the Nori-Weisfeiler strong approximation Theorem we obtain (see [13, Theorem 1.4]):

Theorem 5.1. For large prime $p \equiv 3(\bmod 4)$ and large enough primes $q$ the reduction $\bmod q$ of the quantum representation $\rho_{p}$ exists and has the following properties:
(1) its restriction to $\pi_{1}\left(\Sigma_{g}\right)$ is a surjective homomorphism $f_{p, q}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow$ $P \mathbb{G}_{p}\left(\mathbf{F}_{q}\right)$ onto group of points of $P \mathbb{G}_{p}$ over the finite field $\mathbf{F}_{q}$;
(2) the finite groups $P \mathbb{G}_{p}\left(\mathbf{F}_{q}\right)$ are finite simple groups of Lie type;
(3) $\operatorname{ker} f_{p, q}$ is a characteristic subgroup of $\pi_{1}\left(\Sigma_{g}\right)$.

Remark 5.2. For all but finitely many $q$ the finite groups $P \mathbb{G}_{p}\left(\mathbf{F}_{q}\right)$ are isomorphic to either $P S L\left(N_{g, p}, \mathbf{F}_{q}\right)$ or to projective unitary groups $P U\left(\mathbf{F}_{q^{2}}\right)$. If $q-1$ is coprime with $N_{g, p}$, then $\operatorname{PSL}\left(N_{g, p}, \mathbf{F}_{q}\right)$ has vanishing Schur multiplier

$$
H_{2}\left(P S L\left(N_{g, p}, \mathbf{F}_{q}\right)\right)=0 .
$$

We first show that such quotient homomorphism should be non-elementary:
Proposition 5.3. If $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ is a surjective homomorphism onto a characteristic finite non-trivial quotient $G$, then $f$ is not elementary, namely its thickness is positive.

Proof. From Lemma $4.3 f$ is elementary if and only if there exists some automorphism $\phi$ such that $f=h \circ i_{*} \circ \phi^{-1}$, where $i_{*}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow \pi_{1}\left(H_{g}\right)=\mathbb{F}_{g}$ is the inclusion induced homomorphism and $h: \mathbb{F}_{g} \rightarrow G$. If $\alpha$ is an oriented simple closed curve on $\Sigma_{g}$ let $\bar{\alpha}$ denote the conjugacy class of $\alpha$ in $\pi_{1}\left(\Sigma_{g}\right)$. Let $\alpha$ be a non-separating simple closed curve on $\Sigma_{g}$ which bounds a properly embedded disk in $H_{g}$. Then $i_{*}(\bar{\alpha})=1$, so that $\phi(\bar{\alpha}) \in \operatorname{ker} f$.

Since $\operatorname{ker}(f)$ is a characteristic subgroup of $\pi_{1}\left(\Sigma_{g}\right)$, we also have $\psi(\bar{\alpha}) \subset$ $\operatorname{ker}(f)$ for any automorphism $\psi \in \operatorname{Aut}\left(\pi_{1}\left(\Sigma_{g}\right)\right)$. However, any non-separating simple closed curve $\gamma$ on $\Sigma_{g}$ is the image of $\alpha$ by some homeomorphism of the surface. In particular, the conjugacy classes of the simple closed curves from a standard generator system of $\pi_{1}\left(\Sigma_{g}\right)$ are contained into $\operatorname{ker} f$. This implies that $f$ would be constant, which is a contradiction, thereby proving the claim.
5.2. Non-geometric quotients. We can slightly improve the result above, for the specific case of the homomorphisms $f_{p, q}$ from [13].

Proposition 5.4. Let $f_{p, q}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow P \mathbb{G}_{p}\left(\mathbf{F}_{q}\right)$ be the homomorphisms above, defined by prime $p \equiv 3(\bmod 4)$, and prime $q$ large enough, depending on $p$. Then $\operatorname{ker} f_{p, q}$ is non-geometric, namely it contains no simple closed curve.
Proof. The image of the homotopy class of a based simple closed curve $\gamma$ into $\Gamma\left(\Sigma_{g}^{1}\right)$ is the product of the two commuting left Dehn twists along the curves $\gamma^{+}$ and $\gamma^{-}$obtained by pushing slightly the curve $\gamma$ off the base point towards the left and right, respectively. Therefore the order of $\rho_{p}(\gamma)$ is equal to the order of the image of a Dehn twist by the representation $\rho_{p}$, which is known to be $p$ (see [13]).

Consider the projective matrices $\rho_{p}(\gamma)^{m}$, for $1 \leq m<p$, where $\gamma$ belongs to a finite set of representatives of the set of simple closed on $\Sigma_{g}^{1}$ up to the mapping class group action. Then, for all large enough primes $q$ the reduction $\bmod q$ of these projective matrices are non-trivial. Thus, for every simple closed curve $\gamma$ the elements $f_{p, q}(\gamma)$ have order $p$. In particular, the kernel of $f_{p, q}$ is nongeometric.

Theorem 1.5 is a consequence Theorem 5.1 along with Propositions 5.3 and 5.4.

It is not known what is the largest possible stabilizer of the kernel of an elementary homomorphism. The following is relevant:

Proposition 5.5. Let $\Gamma\left(H_{g}^{1}\right)$ be the mapping class group of the punctured handlebody $H_{g}^{1}$. If $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ is a surjective elementary homomorphism onto a finite quotient whose kernel is invariant by the handlebody subgroup $\Gamma\left(H_{g}^{1}\right)$, then there exists a characteristic finite quotient of $\mathbb{F}_{g}$.

Proof. If $f$ is elementary, then up to composing with an automorphism $\phi$ of $\pi_{1}\left(\Sigma_{g}\right)$, it factors through $i_{*}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow \pi_{1}\left(H_{g}\right)=\mathbb{F}_{g}$, namely $f=h \circ i_{*} \circ \phi$, for some homomorphism $h: \pi_{1}\left(H_{g}\right) \rightarrow G$.

Recall from [18] that the mapping class group $\Gamma\left(H_{g}^{1}\right)$ of the once punctured (or marked) handlebody embeds into the mapping class group $\Gamma\left(\Sigma_{g}^{1}\right)$ of its boundary surface. Moreover, Luft ([27]) showed that the action in homotopy provides an exact sequence:

$$
1 \rightarrow T w\left(H_{g}^{1}\right) \rightarrow \Gamma\left(H_{g}^{1}\right) \rightarrow \operatorname{Aut}^{+}\left(\mathbb{F}_{g}\right) \rightarrow 1
$$

whose kernel is the group of twists, generated by the Dehn twists along meridians of $\Sigma_{g}^{1}$ (i.e. curves bounding disks in $H_{g}^{1}$ ).

As $f$ is invariant by $\Gamma\left(H_{g}^{1}\right)$, the exact sequence above shows that the homomorphism $h$ is also invariant by $\operatorname{Aut}^{+}\left(\mathbb{F}_{g}\right)$. The same argument also work for the full automorphism group.

Remark 5.6. Let $P: \pi_{1}\left(\Sigma_{g+1}\right) \rightarrow \pi_{1}\left(\Sigma_{g}\right)$ be the map induced by a pinch map $P: \Sigma_{g+1} \rightarrow \Sigma_{g}$. Let $\gamma$ be a simple closed curve on $\Sigma_{g}$ based at the point of $\Sigma_{g}$ corresponding to the image of the pinched handle. The based homotopy class of $\gamma^{p}$ can be realized by $p$ parallel copies of $\gamma$ which only intersect at the base point. Observe that $\gamma^{p}$ is the image by the pinch map of a simple closed loop $\widehat{\gamma}$ in $\Sigma_{g+1}$. If $f$ is a homomorphism into a group $G$ and $f(\gamma)$ has order $p$ then $f \circ P(\hat{\gamma})=1$ and hence $f \circ P$ has not anymore non-geometric kernel.
Remark 5.7. The method used in [13] also provides epimorphisms $f: \pi_{1}\left(\Sigma_{g} \backslash\right.$ $B) \rightarrow G$ onto finite simple non-abelian groups $G$, whose kernels are $\Gamma\left(\Sigma_{g} \backslash B\right)$ invariant.

## 6. Stabilizing cohomology groups

We now consider approximated lifts of homomorphisms into $S_{n}$. Let $\gamma_{0} G=$ $G, \gamma_{k+1} G=\left[\gamma_{k} G, G\right]$ denote the lower central series of the group $G$. It is wellknown that $P B_{n}$ is residually torsion-free nilpotent, namely $\bigcap_{k=0}^{\infty} \gamma_{k} P B_{n}=1$ and $A_{k}=\frac{\gamma_{k-1} P B_{n}}{\gamma_{k} P B_{n}}$ are finitely generated torsion-free abelian groups. We denote $B_{n}^{(k)}$ the quotient $B_{n} / \gamma_{k} P B_{n}$. We then have a series of abelian extensions

$$
1 \rightarrow \gamma_{k} P B_{n} / \gamma_{k+1} P B_{n} \rightarrow B_{n}^{(k+1)} \rightarrow B_{n}^{(k)} \rightarrow 1 .
$$

The question whether a homomorphism $f_{k}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow B_{n}^{(k)}$ admits a lift to $f_{k+1}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow B_{n}^{(k+1)}$ can be reformulated in purely cohomological terms. For every $k \geq 1$ there exist examples of homomorphisms $f_{k}$ which admit no lift. Our goal here is to show that the lifting is always possible when $k=0$.

In order to do that, we first show that the pinching map $P$ induces an injection at cohomological level. For the sake of simplicity we only consider the unramified case, but the result works in full generality. Specifically, let $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow G$ be a surjective homomorphism and $A$ be a finitely generated $G$-module, say by means of a homomorphism $\tau: G \rightarrow \operatorname{Aut}(A)$. Then $A$ inherits a $\pi_{1}\left(\Sigma_{g}\right)$-module structure through $\tau \circ f$. Let now $P: \pi_{1}\left(\Sigma_{g+1}\right) \rightarrow \pi_{1}\left(\Sigma_{g}\right)$ be the pinch map, which is given in convenient basis $\left\{\alpha_{i}, \beta_{i}\right\}_{i=1, \ldots, g+1}$ and $\left\{a_{i}, b_{i}\right\}_{i=1, \ldots, g}$ by

$$
P\left(\alpha_{i}\right)=a_{i}, P\left(\beta_{i}\right)=b_{i}, i \leq g, P\left(\alpha_{g+1}\right)=P\left(\beta_{g+1}\right)=1 .
$$

Then $f \circ P: \pi_{1}\left(\Sigma_{g+1}\right) \rightarrow G$ provides a $\pi_{1}\left(\Sigma_{g+1}\right)$-module structure on $A$ by means of $\tau \circ f \circ P$. Our main result is the following:

Proposition 6.1. The homomorphism

$$
P^{*}: H^{2}\left(\pi_{1}\left(\Sigma_{g}\right), A\right) \rightarrow H^{2}\left(\pi_{1}\left(\Sigma_{g+1}\right), A\right)
$$

is injective.
Proof. Consider a normalized 2-cocycle $w: \pi_{1}\left(\Sigma_{g}\right) \times \pi_{1}\left(\Sigma_{g}\right) \rightarrow A$, namely such that $w(x, 1)=w(1, x)=0$, whose cohomology class lies in $\operatorname{ker} P^{*}$. Then the image 2 -cocycle $P^{*} w$ is given by $P^{*} w(x, y)=w(P(x), P(y))$. By hypothesis it is exact, namely of the form

$$
P^{*} w(x, y)=\delta \phi(x, y)=x \cdot \phi(y)-\phi(x y)+\phi(x),
$$

where $\phi: \pi_{1}\left(\Sigma_{g+1}\right) \rightarrow A$ is a 1-cochain. Let $H=\left\langle\alpha_{i}, \beta_{i}, i \in\{1,2, \ldots, g\}\right\rangle$ and $K=\left\langle\alpha_{g+1}, \beta_{g+1}\right\rangle$ be the subgroups of $\pi_{1}\left(\Sigma_{g+1}\right)$ generated by the respective elements and note that they are free groups. We observe that whenever $x \in H$ and $u, v \in K$ we have:

$$
\begin{gathered}
\phi(x u)=x \cdot \phi(u)+\phi(x)-w(P(x), P(u))=x \cdot \phi(u)+\phi(x), \\
\phi(u x)=u \cdot \phi(x)+\phi(u)-w(P(u), P(x))=\phi(x)+\phi(u), \\
\phi(u v)=u \cdot \phi(v)+\phi(u)-w(P(u), P(v))=\phi(v)+\phi(u) .
\end{gathered}
$$

The last equation implies that $\phi\left(u^{-1}\right)=-\phi(u)$ for $u \in K$, so that

$$
\phi\left(\left[\alpha_{g+1}, \beta_{g+1}\right]\right)=0
$$

We aim at analyzing the restriction of $\phi$ to $H$. Set

$$
R=\prod_{i=1}^{g}\left[\alpha_{i}, \beta_{i}\right] \in H
$$

Then

$$
0=\phi(1)=\phi\left(R\left[\alpha_{g+1}, \beta_{g+1}\right]\right)=R \cdot \phi(R)=P(R) \cdot \phi(R)=\phi(R) .
$$

Consider further $x \in H$. By above we have

$$
\begin{aligned}
\phi\left(x R x^{-1}\right) & =x R \cdot \phi\left(x^{-1}\right)+\phi(x)-P^{*} w\left(x R, x^{-1}\right) \\
& =x R \cdot\left(x^{-1} \cdot\left(P^{*} w\left(x, x^{-1}\right)-\phi(x)\right)+\phi(x)-P^{*} w\left(x R, x^{-1}\right)\right. \\
& =x R x^{-1} \cdot P^{*} w\left(x, x^{-1}\right)-x R x^{-1} \cdot \phi(x)+\phi(x)-P^{*} w\left(x R, x^{-1}\right) \\
& =x R x^{-1} \cdot P^{*} w\left(x, x^{-1}\right)-P^{*} w\left(x R, x^{-1}\right),
\end{aligned}
$$

the last equality following from the fact that $P\left(x R x^{-1}\right)=1$ thereby $x R x^{-1}$ is acting trivially on $A$. Recall that $w$ is a 2 -cocycle and hence satisfies

$$
x \cdot w(y, z)-w(x y, z)+w(x, y z)-w(x, y)=0 .
$$

Its pullback verifies then

$$
\begin{aligned}
\phi\left(x R x^{-1}\right) & =x R x^{-1} \cdot P^{*} w\left(x, x^{-1}\right)-P^{*} w\left(x R, x^{-1}\right)= \\
& =P^{*} w\left(x R x^{-1}, x\right)-P^{*} w\left(x R x^{-1}, 1\right)=w\left(P\left(x R x^{-1}\right), P(x)\right)=0 .
\end{aligned}
$$

It follows that $\phi\left(x R^{-1} x\right)=0$.

Let $L \triangleleft H$ be the normal subgroup generated by $R$ within $H$. Every element of $L$ can be written as a product of conjugates of $R$ and $R^{-1}$ within $H$. If $x, y \in L$ and $\phi(x)=\phi(y)=0$, then

$$
\phi(x y)=x \cdot \phi(y)+\phi(x)-w(P(x), P(y))=0,
$$

because $P(x)=P(y)=1$. By induction on the number of conjugates, we derive that $\left.\phi\right|_{L}: L \rightarrow A$ is trivial.

Now, if $x=u y$, where $u \in L$, then

$$
\phi(x)=\phi(u y)=u \phi(y)+\phi(u)-w(P(u), P(y))=\phi(y),
$$

because $P(u)=1$. It follows that $\phi$ is constant on right cosets of $L$, so that $\phi$ induces a well-defined map $\bar{\phi}: H / L \rightarrow A$. Moreover the restriction of the homomorphism $P: \pi_{1}\left(\Sigma_{g+1}\right) \rightarrow \pi_{1}\left(\Sigma_{g}\right)$ to $H$ induces an isomorphism of $\bar{P}$ : $H / L \rightarrow \pi_{1}\left(\Sigma_{g}\right)$.

Observe that the 1-chain $\bar{\phi}$ satisfies for all $x, y \in H / L$

$$
\delta \bar{\phi}(x, y)=P^{*} w(\tilde{x}, \tilde{y})=w(\bar{P}(x), \bar{P}(y)),
$$

where $\tilde{x}, \tilde{y}$ are lifts in $H$ of $x, y$, respectively. It follows that $w$ is exact, as claimed.

Then using Proposition 6.1 we obtain a conceptual (without calculation) proof of the following:

Proposition 6.2. Anyhomomorphism $f: \pi_{1}\left(\Sigma_{g}\right) \rightarrow S_{n}$ has alift $f_{1}: \pi_{1}\left(\Sigma_{g}\right) \rightarrow$ $B_{n}^{(1)}$.

Proof. Let $\mathcal{E}_{1}$ denote the extension with abelian kernel:

$$
1 \rightarrow A_{1} \rightarrow B_{n}^{(1)} \rightarrow S_{n} \rightarrow 1
$$

whose characteristic class $c_{\varepsilon_{1}}$ is denoted $e_{1} \in H^{2}\left(S_{n}, A_{1}\right)$.
Observe first that $f$ admits a lift $f_{1}$ to $B_{n}^{(1)}$ if and only if the pull-back extension $f^{*} \varepsilon_{1}$ admits a section $s$ over $\pi_{1}\left(\Sigma_{g}\right)$. This amounts to saying that $f^{*} \varepsilon_{1}$ is a split extension which is equivalent with $c_{f^{*} \varepsilon_{1}}=f^{*} e_{1}=0 \in H^{2}\left(\pi_{1}\left(\Sigma_{g}\right), A_{1}\right)$, where $A_{1}$ has a $\pi_{1}\left(\Sigma_{g}\right)$-module structure induced by $f$.

On the other hand Theorem 3.11 shows that after sufficiently many stabilizations $f \circ P_{g, h}$ lifts to a homomorphism $F$ into $B_{n}$, where $P_{g, h}: \pi_{1}\left(\Sigma_{g+h}\right) \rightarrow$ $\pi_{1}\left(\Sigma_{g}\right)$ is the pinch map of the last $h$ handles. Let $Q^{(1)}: B_{n} \rightarrow B_{n}^{(1)}$ be the quotient by $\gamma_{1} P B_{n}$. Then $Q^{(1)} \circ F$ is a lift of $f \circ P_{g, h}$ to $B_{n}^{(1)}$.

The previous argument implies that $\left(f \circ P_{g, h}\right)^{*} \mathcal{E}_{1}$ is a split extension over $\pi_{1}\left(\Sigma_{g+h}\right)$ and hence $P_{g, h}^{*} \circ f^{*} e_{1}=0 \in H^{2}\left(\pi_{1}\left(\Sigma_{g+h}\right), A_{1}\right)$. Proposition $6.1 \mathrm{im}-$ plies that $f^{*} e_{1}=0 \in H_{2}\left(\pi_{1}\left(\Sigma_{\mathrm{g}}\right), A_{1}\right)$ and thus the claim follows.

Remark 6.3. The lifts $f_{1}$ of $f$ modulo $A_{1}$-conjugacy are in one-to-one correspondence with the section $s$ of $f^{*} \mathcal{E}_{1}$, and thus they form an affine space with
underlying vector space $H^{1}\left(\pi_{1}\left(\Sigma_{g}\right), A_{1}\right)$. It seems possible that for any $f$ there exists some lift $f_{1}$ of $f$ which further can be lifted to $B_{n}^{(2)}$.

## 7. Spherical functions and proof of Theorem 1.8

7.1. Pullback spherical functions from Lie groups. A key algebraic object in this section is the representation space

$$
M_{G}(\Sigma, B) \subseteq \operatorname{Hom}\left(\pi_{1}(\Sigma \backslash B), G\right) / G,
$$

containing the subspace $M_{G}(\Sigma, B, \mathbf{c})$ of classes of representations with prescribed conjugacy classes of peripheral loops. There are analogous moduli spaces of mapping class group orbits:

$$
\mathcal{M}_{G}(\Sigma, B)=\Gamma(\Sigma \backslash B) \backslash M_{G}(\Sigma, B) .
$$

We observed in the first section that the corresponding discrete spaces for $G=$ $B_{n}$ correspond to (strong) equivalence classes of braided surfaces. One should note that $G=\Gamma(S)$ corresponds to achiral Lefschetz fibrations with fiber $S$. Our aim is to construct functions on these spaces, corresponding in particular to invariants of braided surfaces.

In order to treat the unbranched case $B=\emptyset$ we observe that we have a natural embedding:

$$
M_{G}(\Sigma, \emptyset) \subset \operatorname{Hom}\left(\pi_{1}(\Sigma \backslash\{p\}), G\right) / G,
$$

which provides functions on $M_{G}(\Sigma, \emptyset)$ by restricting functions defined on the right hand side space.

We construct spherical functions on representation spaces associated to discrete groups by pullback of spherical functions defined on Lie groups. Let $R: G \rightarrow \mathbb{G}$ be a homomorphism representation of $G$ into the Lie group $\mathfrak{G}$. To any $f: \pi_{1}(\Sigma \backslash B) \rightarrow G$ we associate the homomorphism $R_{*}(f)=R \circ f:$ $\pi_{1}(\Sigma \backslash B) \rightarrow \mathfrak{G}$. This induces a map

$$
R_{*}: M_{G}(\Sigma, B) \rightarrow M_{\mathscr{G}}(\Sigma, B) .
$$

Obviously the map $R_{*}$ only depends on the class of $R$ inside $\operatorname{Hom}(G, \mathfrak{G}) /(\mathfrak{G}$. Now, the representation variety $M_{\mathscr{E}}(\Sigma, B)$ was the subject on intensive study, when $\mathfrak{G}$ is a Lie group.

If $B \neq \emptyset$, then $M_{G}(\Sigma, B)=G^{m} / G$, where $m$ is the rank of the free group $\pi_{1}(\Sigma \backslash B)$ and $G$ acts diagonally by conjugation on $G^{m}$. Note that $M_{G}(\Sigma, B)$ can also be identified with the double coset space $G \backslash G^{m+1} / G$, where $G$ is diagonally embedded in $G^{m+1}$.

Let now introduce some terminology from representation theory. If $\rho$ is a unitary representation of a group $H$ in a Hilbert space $V$, then a matrix coefficient is the function $\phi(x)=\langle\rho(x) v, w\rangle$, where $v, w \in V$. Let $L(H)$ be the vector space of complex functions on $H$. If $K \subseteq H$ is a subgroup, we denote by $L(K \backslash H / K) \subset L(H)$ the subspace of functions which are bi- $K$-invariant, namely such that $\phi\left(k_{1} x k_{2}\right)=\phi(x)$, for $k_{i} \in K, x \in H$. A matrix coefficient
$\phi(x)=\langle\rho(x) v, w\rangle$ is bi- $K$-invariant if $v, w$ belong to the space of $K$-invariants vectors $V^{K}$.

Observe first that in the case when $V$ is finite dimensional complex vector space, the same formula define a bi- $K$-invariant function, even if $\langle$,$\rangle is only a$ Hermitian form on $V$, not necessarily positive definite. The functions obtained this way will be called $K$-spherical functions on $H$; we will add unitary if we want to specify that the Hermitian form is positive definite. Carrying this construction for the pair $K=G$ and $H=G^{k}$ we obtain a family of complex functions on $G \backslash G^{k} / G$, called spherical functions. The main question addressed here is to what extent the spherical functions separate points of representation spaces.
7.2. Compact Lie groups. We can organize spherical functions by using the $\operatorname{map} R_{*}$ associated to a representation of $G$ into some compact group $(\mathbb{G}$ in order to pull back spherical functions from $\mathfrak{G s}^{k}$. The following should be well-known, but for lack of references, we sketch the proof:

Proposition 7.1. Let $K \subset H$ be either finite groups or compact connected Lie groups. Then the unitary $K$-spherical functions on $H$ separate the points of $K \backslash H / K$.

Proof. Let $L(H / K)$ be the Hilbert space of complex valued functions on $H / K$, which is endowed with the tautological left action by $H$.

Consider first the case when $H$ is finite. Write $L(H / K)$ as a sum of irreducible representations $V_{j}$, along with their multiplicities $m_{j}$ :

$$
L(H / K)=\oplus_{j \in J} V_{j}^{m_{j}}
$$

By Wielandt's lemma (see e.g. [7], Thm.3.13.3), the number of $K$-orbits in $H / K$ is equal to $\sum_{j \in J} m_{j}^{2}$, so that

$$
\operatorname{dim} L(K \backslash H / K)=\sum_{j \in J} m_{j}^{2}
$$

Now the Frobenius reciprocity (see [41], Thm. 1.4.9) gives us

$$
m_{j}=\operatorname{dim} V_{j}^{K}
$$

Consider the matrix coefficients associated to irreducible representations of $\mathfrak{G}$ into finite dimensional vector spaces $V$ and vectors $v, w$ arising from a basis of $V^{K}$. According to ([7], Lemma 3.6.3) matrix coefficients of this form are orthonormal in $L(H)$. Since they are $\sum_{j \in J} m_{j}^{2}$ elements of $L(K \backslash H / K)$, it follows that they form a basis of $L(K \backslash H / K)$. In particular, the basis functions separate points of $K \backslash H / K)$, as the set of all functions in $L(K \backslash H / K)$ does separate.

The proof in the case where $H$ is a compact Lie group follows the same lines as in the finite case, now using instead the Peter-Weyl theorem. For instance, matrix coefficients are dense in the space $L^{2}(G)$, the $H$-spherical functions are spanning the space of $L^{2}$-class functions while $L^{2}(G)=\oplus W^{\mathrm{dim} W}$ is the direct sum of all irreducible representations $W$ of $G$ with multiplicity equal to their dimension. We leave details to the reader.

This method provides an infinite family of spherical functions for the case where $M_{\mathscr{G}}(\Sigma, B)=\mathscr{G} \backslash\left(G^{k} / \mathfrak{G}\right.$, when $B \neq \emptyset$ and $\pi_{1}(\Sigma \backslash B)$ is a free group of rank $k-1$. Specifically we consider the set $V_{i}, i \in \widehat{\mathfrak{G}}$ of all isomorphisms types of irreducible representations of $\mathfrak{G}$. Then $V_{i_{1}} \otimes \cdots V_{i_{k}}$ form a representation of $\mathscr{G}^{k}$. We should restrict to those unitary representations for which $V_{i_{1}} \otimes \cdots \otimes V_{i_{k}}$ has a fixed $\mathfrak{G}$-vector. For each $u, v \in B_{I}$ in some basis $B_{I}$ of the space of $\mathfrak{G}$-invariants $H^{0}\left(\mathscr{G}, V_{i_{1}} \otimes \cdots \otimes V_{i_{k}}\right)$ we have the spherical function

$$
\phi_{u, v, I}(x)=\left\langle V_{i_{1}} \otimes \cdots \otimes V_{i_{k}}(x) u, v\right\rangle,
$$

where $I=\left(i_{1}, \ldots, i_{k}\right)$. The (infinite) set of all such functions will separate points of $M_{\mathscr{G}}(\Sigma, B)=\mathscr{G} \backslash\left(G^{k} /(\mathscr{G}\right.$. It is now easy to construct a single function taking values in the series in several variables with matrix coefficients:

$$
\left.\Phi(x)=\sum_{I,(u, v)} \frac{1}{I!}\left(\phi_{I, u, v}(x)\right)_{u, v \in B_{I}}\right) X^{I} .
$$

A direct consequence of Proposition 7.1 is:
Proposition 7.2. Assume that $\mathfrak{G}$ is a compact Lie group. Then $\Phi$ is a complete invariant for $M_{\mathscr{G}}(\Sigma, B)$, namely it separates its points: $\Phi(x)=\Phi(y)$ if and only if $x=y$.

Neretin ([31]) considered the case $\mathfrak{G S}=S U(2)$ and expressed (a modified version of) the algebraic function $\Phi$ as a determinant. In this case we know that $B_{I}$ is indexed by the set of partitions $\alpha=\left(\alpha_{s t}\right)_{s, t=1, \ldots, k}$ with

$$
\sum_{t} \alpha_{s t}=i_{s} .
$$

Then we consider

$$
\Phi_{N}=\sum_{I,\left(\alpha_{s t}\right)} \frac{1}{\alpha!\beta!} \prod_{s, t} \mathbf{x}^{\alpha} \mathbf{y}^{\beta}\left(\phi_{I, \alpha, \beta}\right),
$$

where we set $\mathbf{x}^{\alpha}=\prod_{s, t} x_{s t}^{\alpha_{s t}}, \alpha!=\prod_{s, t} \alpha_{s t}$ !. Then the closed formula of [31] reads:

$$
\Phi_{N}(A)=\operatorname{det}\left(1-A X A^{\perp} Y\right)^{-1 / 2}
$$

for $A \in S U(2)^{k}$, where $X=\left(X_{i j}\right), Y=\left(Y_{i j}\right)$ are matrices of blocks of the form $X_{i j}=\left(\begin{array}{cc}0 & x_{i j} \\ -x_{i j} & 0\end{array}\right), Y_{i j}=\left(\begin{array}{cc}0 & y_{i j} \\ -y_{i j} & 0\end{array}\right)$, and $x_{i j}, y_{i j}$ are variables.

In particular we obtain:
Proposition 7.3. To any representation $R: G \rightarrow S U(2)$ of the group $G$ we have associated a polynomial valued invariant map $\Phi_{R}: M_{G}(\Sigma, B) \rightarrow \mathbb{C}[X, Y]$, given by:

$$
\Phi_{R}(a)=\operatorname{det}\left(1-R(A) X R(A)^{\perp} Y\right) .
$$

In particular, this holds when the group $G$ is the braid group $B_{3}$ and $R$ is the Burau representation for a parameter within the unit circle $U(1)$, the map $\Phi_{R}$ providing then invariants of braided surfaces of degree 3 with nontrivial branch locus.

Often we can reduce the matrix-valued function $\Phi$ to a finite polynomial in more variables. In fact, for any $\mathfrak{G}$ as above $M_{\mathfrak{G}}(\Sigma, B)$ is homeomorphic to a finite CW complex. In particular it admits an embedding $\varphi: M_{\mathfrak{G}}(\Sigma, B) \rightarrow \mathbb{R}^{n}$. The components of $\varphi$ form therefore a complete invariant for $M_{\mathscr{5}}(\Sigma, B)$ and so there is a much simpler invariant than $\Phi$. Nevertheless we lack an exact form of $\varphi$, in general.

In many interesting cases $\mathfrak{G} \backslash\left(\mathscr{S}^{k} /(\mathscr{G}\right.$ has the structure of an (affine) algebraic variety over $\mathbb{C}$. Thus we can expect to have a nice algebraic embedding $\varphi$. Such an embedding can be obtained from a basis of the algebra of regular functions on $M_{\mathfrak{G}}(\Sigma, B)$.

This is the case of $\mathfrak{G}=U(n)$, for instance. Let $A=\left(A_{1}, A_{2}, \ldots, A_{k}\right) \in U(n)^{k}$, $I=\left\{i_{1}, i_{2}, \ldots, i_{j}\right\}, 1 \leq i_{1}<i_{2}<\ldots<i_{j} \leq k$ and $\varepsilon: I \rightarrow\{1, \star\}$. We denote by

$$
A^{I ; \varepsilon}=A_{i_{1}}^{\varepsilon\left(i_{1}\right)} A_{i_{2}}^{\varepsilon\left(i_{2}\right)} \cdots A_{i_{j}}^{\varepsilon\left(i_{j}\right)},
$$

where $A^{\star}$ denotes $\left(A^{-1}\right)^{T}$. Procesi proved in ([38], Thm. 11.2) that the set of trace functions

$$
\left\{\operatorname{tr}\left(A^{I ; \varepsilon}\right) \mid I \subseteq\{1,2, \ldots, k\}, \varepsilon: I \rightarrow\{1, \star\}\right\}
$$

over all possible $I$ and $\varepsilon$ represent a basis of the algebra of regular functions on $U(n) \backslash U(n)^{k} / U(n)$. Let $x_{i}$ be noncommutative variables,

$$
X^{I ; \varepsilon}=x_{i_{1}}^{\bar{\varepsilon}\left(i_{1}\right)} x_{i_{2}}^{\bar{\varepsilon}\left(i_{2}\right)} \cdots A_{x_{j}}^{\bar{\varepsilon}\left(i_{j}\right)},
$$

where $\bar{\varepsilon}(i)=\varepsilon(i)$, when the later equals 1 and -1 , otherwise. Then the noncommutative Laurent polynomial

$$
\Psi(A)=\sum_{I, \varepsilon} \operatorname{tr}\left(A^{I ; \varepsilon}\right) X^{I ; \varepsilon}
$$

separates points of $U(n) \backslash U(n)^{k} / U(n)$.
Proposition 7.4. To any unitary representation $R: G \rightarrow U(n)$ of the group $G$ we have associated a noncommutative Laurent polynomial valued invariant map $\Psi_{R}$ on $M_{G}(\Sigma, B)$, given by:

$$
\Psi_{R}(a)=\Psi(R(a)) .
$$

In particular, this holds when the group $G=B_{n}$ and the $R$ is the Burau representation for a parameter within the unit circle $U(1)$, the map $\Psi_{R}$ providing then invariants of braided surfaces of degree $n$ with nontrivial branch locus.

Remark 7.5. There is a similar result for the noncommutative polynomial

$$
\Psi_{R}^{\prime}(A)=\sum_{I \subseteq\{1,2, \ldots, k\}} \operatorname{tr}\left(A^{I}\right) X^{I}
$$

associated to a linear representation $R: G \rightarrow G L(n)$ of the group $G$, which now separates points of $G L(n) \backslash G L(n)^{k} / G L(n)$, following ([38], section 3).
7.3. Spherical functions for discrete groups. Consider now the case of a discrete group $G$. As observed above it is enough to consider that $B \neq \emptyset$, so that $M_{G}(\Sigma, B)=G \backslash G^{k} / G$ is a space of cosets. In contrast to the case of a compact group $G$, now spherical functions do not necessarily separate points of $M_{G}(\Sigma, B)$.

For a discrete group $H$ we denote by $\hat{H}$ its profinite completion. There is a natural map $i: H \rightarrow \widehat{H}$ which is injective if and only if $H$ is residually finite. If $K \subseteq H$ is a subgroup, we denote by $\bar{K}$ the closure of $i(K)$ into $\widehat{H}$. The map $i$ induces a map between cosets

$$
\iota: K \backslash H / K \rightarrow \bar{K} \backslash \widehat{H} / \bar{K}
$$

Definition 7.6. Two cosets of $K \backslash H / K$ are profinitely separated if their images by $\iota$ are distinct.

One case of interest is when $K=G$ is embedded diagonally within $H=$ $G^{k}$. It is easy to see that $\widehat{G^{k}}$ is isomorphic to $\widehat{G}^{k}$ and we will identify them in the sequel. If $G$ is embedded diagonally into $G^{k}$, then its closure $\bar{G}$ into $\widehat{G}^{k}$ is isomorphic to the image of $\widehat{G}$ into $\widehat{G}^{k}$ by its diagonal embedding. Then the map c from above

$$
\iota: G \backslash G^{k} / G \rightarrow \widehat{G} \backslash \widehat{G}^{k} / \widehat{G}
$$

sends a double coset $\bmod G$ into its class mod $\widehat{G}$. This notion encompasses more classic notions, as the conjugacy separability of the group $G$, when we take $k=2$ above.

The main result of this section is:
Theorem 7.7. Assume that $H$ is finitely generated and $K \subseteq H$ is a subgroup. Two cosets of $K \backslash H / K$ are separated by some Hermitian spherical function if and only if they are profinitely separated.

Proof. Let $x$ and $y$ be cosets which cannot be distinguished by spherical functions associated to Hermitian representations of $H$, and in particular by spherical functions associated to finite representations. Let now $F$ be a finite quotient of $H, K_{F}$ be the image of $K$ in $F$. Proposition 7.1 shows that spherical functions associated to linear representations of $F$ separately precisely the points of $K_{F} \backslash F / K_{F}$. Then the images of $x$ and $y$ should coincide in $K_{F} \backslash F / K_{F}$, for any $F$ and hence $\iota(x)=\iota(y)$.

Conversely, a finite dimensional Hermitian representation $V$ of $H$ is defined over some finitely generated ring $\mathcal{O} \subset \mathbb{C}$. By enlarging $\mathcal{O}$ we can suppose that $\langle$,$\rangle has entries from \mathcal{O}$. We can assume, by further enlarging $\mathcal{O}$, that there is a basis $B$ of $V^{H}$ consisting of vectors whose coordinates belong to $\mathcal{O}$.

Suppose that for some $H$-invariant vectors $u$ and $v$ the spherical function $\phi_{u, v}$ separates the cosets $x$ and $y$. We can take then $u, v \in \mathcal{O}\langle B\rangle$. Further, for all but finitely many prime ideals $\mathfrak{p}$ in $\mathcal{O}$, we have

$$
\phi_{u, v}(x) \not \equiv \phi_{u, v}(y)(\bmod \mathfrak{p}) \in \mathcal{O} / \mathfrak{p} .
$$

Now let $W$ be the reduction mod $\mathfrak{p}$ of the $H$ representation on $V$. These are finite representations and the invariant subspace $W^{K}$ contains the reduction $\bmod \mathfrak{p}$ of $V^{K}$. Denote by $\bar{w}$ the reduction $\bmod \mathfrak{p}$ of the vector $w \in \mathcal{O}\langle B\rangle$. It follows that $\bar{u}$ and $\bar{v}$ belong to $W^{H}$. As spherical functions are bilinear, for any $z \in H$ we have:

$$
\phi_{\bar{u}, \bar{v}}(z) \equiv \phi_{u, v}(z) \in \mathcal{O} / \mathfrak{p} .
$$

In particular, the spherical function $\phi_{\bar{u}, \bar{v}}$ associated to a finite representation distinguishes $x$ from $y$. This implies that $x$ and $y$ are profinitely separated.
Remark 7.8. The profinite separability of all cosets in $B_{n} \backslash B_{n}^{k} / B_{n}$ and their mapping class group generalizations seems to be widely open.
7.4. Hurwitz equivalence. To step from strong equivalence to the usual (i.e. Hurwitz) equivalence amounts of studying the action of $\Gamma(\Sigma \backslash B)$ on the vector space of functions on $M_{G}(\Sigma, B)$. However the previous approach using pullbacks of spherical functions from compact Lie groups leads to a dead end. In fact, we have the following result due to Goldman for $S U(2)$ and to Pickrell and Xia for a general compact group:

Theorem 7.9 ([35, 36]). If $\mathfrak{G}$ is a compact connected Lie group and $\Sigma \backslash B$ is hyperbolic then the action of $\Gamma(\Sigma \backslash B)$ on $M_{\mathscr{G}}\left(\Sigma_{g}, B\right)$ is ergodic with respect to the quasi-invariant measure.

In particular there are no continuous functions on $M_{\mathfrak{G}}\left(\Sigma_{g}, B\right)$ which are invariant under the $\Gamma(\Sigma \backslash B)$ action, other than the constants. Pull-backs of spherical functions associated to compact groups could only provide constant functions on $\mathcal{M}_{G}(\Sigma, B)$. In order to get further insight by this method we have to step to non-compact Lie groups and the corresponding higher Teichmüller theory. As in the previous section, components of $\mathcal{M}_{\mathscr{G}}(\Sigma, B)$ which have a CW complex structure, as Hitchin components, will provide functions on the corresponding subsets of $\mathcal{M}_{G}(\Sigma, B)$.
